User and Programmers' Guide to the X Ray-Tracing Package McXtrace, version 3.8

E. B. Knudsen, P. Willendrup, E. Farhi, K. Lefmann, S. Schmidt

September, 2026

The software package McXtrace is a tool for carrying out highly complex Monte Carlo ray-tracing simulations of X-ray beamlines to high precision. The simulations can compute all aspects of the performance of instruments and can thus be used to optimize the use of existing equipment, design new instrumentation, and carry out virtual experiments for e.g. training, experimental planning or data analysis. McXtrace is based on a unique design, inherited from its sister McStas, where an automatic compilation process translates high-level textual instrument descriptions into efficient ANSI-C code. This design makes it simple to set up typical simulations and also gives essentially unlimited freedom to handle more unusual cases.

This report constitutes the reference manual for McXtrace, and, together with the manual for the McXtrace components, it contains full documentation of all aspects of the program. It covers the various ways to compile and run simulations, a description of the meta-language used to define simulations, and some example simulations performed with the program.

This report documents McXtrace version 3.8, released September, 2026

Preface and acknowledgements

This document contains information on the Monte Carlo x-ray tracing program McXtrace version 3.8, building on the initial release in October 1998 of the neutron ray tracing program McStas version 1.0 as presented in Ref. [LN99]. The reader of this document is expected to have some knowledge of x-ray and/or neutron scattering, whereas only little knowledge about simulation techniques is required. In a few places, we also assume familiarity with the use of the C programming language and UNIX/Linux.

Support has been kindly given by SAXLAB Aps. through its CEO Karsten Joensen as well the ESRF and MAX IV Laboratory. We acknowledge all contributing parties.

In case of errors, questions, or suggestions, please do not hesitate to contact the team and the community by either writing to the user mailing list `mcxtrace-users@mcxtrace.org`, consulting the McXtrace home page [Mcx], or leaving a note on the McXtrace facebook page <https://www.facebook.com/McXtrace>. A special bug/request reporting service is available [Mcz].

If you **appreciate** this software, please subscribe to the `mcxtrace-users@mcxtrace.org` email list, send us a smiley message, and contribute to the package.

We encourage you to refer to this software when publishing result with the following citation: E. B. Knudsen, et. al., *Journal of Applied Crystallography*, vol. 46, 2013.

Third party software included in the distribution McXtrace is:

- perl Math::Amoeba from John A.R. Williams `J.A.R.Williams@aston.ac.uk`.
- perl Tk::Codetext from Hans Jeuken `haje@toneel.demon.nl`.
- and optionally PGPLOT from Tim Pearson `tjp@astro.caltech.edu`.

The McXtrace project was initially supported by Det Strategiske Forskningsråd through the NaBiIT programme. Partners in this joint venture were:

- Materials Research Division, Risø DTU, Roskilde, Denmark.
- Niels Bohr Institute, University of Copenhagen, Denmark.
- Faculty of Life Sciences, University of Copenhagen, Denmark.
- SAXLAB ApS. Lundtofte, Denmark.
- ESRF, Grenoble, France.

1. Introduction to McXtrace

Efficient design and optimization of x-ray beamlines are formidable challenges. In many cases Monte Carlo techniques are well matched to meet these challenges. McXtrace is an effort to port the framework provided to the neutron scattering community by the McStas package, to x-ray scattering. McStas has, since its inception in October '98, been used successfully at all major neutron scattering facilities in the world. A particular power of McStas is its geometry engine, which has been adopted by McXtrace, with little modification. The device library of McXtrace is not yet as complete as its sibling McStas but is growing rapidly. At the time of writing it is complete enough to be able to perform simulations approximating any standard beamline.

McXtrace is a fast and versatile software tool. It is based on a meta-language specially designed for x-ray (and neutron) simulation. Specifications are written in this language by users and automatically translated into efficient simulation codes in ANSI-C. The present version supports both continuous and pulsed source beamlines, and includes a library of standard components with total around 100 components.

The McXtrace package is written in ANSI-C and is freely available for download from the McXtrace website [Mcx]. The package is actively developed and supported by Physics Department, Technical University of Denmark, Kgs. Lyngby, Denmark., Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark., European Synchrotron Radiation Facility, Grenoble, France.and SAXSLAB Aps. The system is tested and is supplied with examples and documentation. Besides this manual, a separate component manual exists which details each individual component separately.

1.1. Development of Monte Carlo x-ray simulation

Monte Carlo simulation of x-ray instrumentation has been used for many years — in particular the SHADOW package [WCC94; Rio+11] has found widespread use, and is still actively developed, yet has some limitations. *Ray*[Sch08] and *Xtrace*[Bau+07] are other packages using the same basic techniques.

What sets McXtrace apart is, among other things, its open source development strategy and its inherent modularity. This combination lets independent scientists work indepently on separate modules that they have use for, and contribute to the whole with only a small effort.

1.2. Scientific background

What makes scientists happy? Probably to collect good quality data, pushing beamlines to their limits, and fit that data to physical models. Among available measurement techniques, x-ray scattering provides a large variety of beamlines to probe structure and dynamics of all kinds of samples.

Achieving a satisfactory experiment on the best beamline is not all. Once collected, the data analysis process raises some questions concerning the signal: what is the background signal? What proportion of coherent and incoherent scattering has been measured? What are the contributions from the sample geometry, the container, the sample environment, and generally the beamline itself? And last but not least, how does multiple scattering affect the signal? Most of the time, the physicist will elude these questions using rough approximations, or applying analytical corrections [Cop+86]. Monte-Carlo techniques provide a mean to evaluate some of these quantities. The technicalities of Monte-Carlo simulation techniques are explained in detail in chapter 4.

1.2.1. The goals of McXtrace

Initially, the McStas project and hence also the present subject the McXtrace project had four main objectives that determined its design.

Correctness. It is essential to minimize the potential for bugs in computer simulations. If a word processing program contains bugs, it will produce bad-looking output or may even crash. This is a nuisance, but at least you know that something is wrong. However, if a simulation contains bugs it produces wrong results, and unless the results are far off, you may not know about it! Complex simulations involve hundreds or even thousands of lines of formulae, making debugging a major issue. Thus the system should be designed from the start to help minimize the potential for bugs to be introduced in the first place, and provide good tools for testing to maximize the chances of finding existing bugs.

Flexibility. When you commit yourself to using a tool for an important project, you need to know if the tool will satisfy not only your present, but also your future requirements. The tool must not have fundamental limitations that restrict its potential usage. Thus the McXtrace systems needs to be flexible enough to simulate different kinds of instruments as well as many different kind of optical components, and it must also be extensible so that future, as yet unforeseen, needs can be satisfied.

Power. “*Simple things should be simple; complex things should be possible*”. New ideas should be easy to try out, and the time from thought to action should be as short as possible. If you are faced with the prospect of programming for two weeks before getting any results on a new idea, you will most likely drop it. Ideally, if you have a good idea at lunch time, the simulation should be running in the afternoon.

Efficiency. Monte Carlo simulations are computationally intensive, hardware capacities are finite (albeit impressive), and humans are impatient. Thus the system must assist in producing simulations that run as fast as possible, without placing unreasonable burdens on the user in order to achieve this.

1.3. The design of McXtrace

In order to meet these ambitious goals, it was decided that McXtrace should be based on its own meta-language, specially designed for simulating scattering beamlines. Simulations are written in this meta-language by the user, and the McXtrace compiler automatically translates them into efficient simulation programs written in ANSI-C.

In realizing the design of McXtrace, the task was separated into four conceptual layers:

1. Modeling the physical processes of scattering, *i.e.* the calculation of the fate of a photon that passes through the individual components of the beamline (absorption, scattering at a particular angle, etc.)
2. Modeling of the overall beamline geometry, mainly consisting of the type and position of the individual components.
3. Accurate calculation, using Monte Carlo techniques, of beamline properties such as resolution function from the result of ray-tracing of a large number of photons. This includes estimating the accuracy of the calculation.
4. Presentation of the calculations, graphical or otherwise.

Though obviously interrelated, these four layers can be treated independently, and this is reflected in the overall system architecture of McXtrace. The user will in many situations be interested in knowing the details only in some of the layers. For example, one user may merely look at some results prepared by others, without worrying about the details of the calculation. Another user may simulate a new instrument without having to reinvent the code for simulating the individual components in the instrument. A third user may write an intricate simulation of a complex component, e.g. a detailed description of a high resolution fast chopper, and expect other users to easily benefit from his/her work, and so on. McXtrace attempts to make it possible to work at any combination of layers in isolation by separating the layers as much as possible in the design of the system and in the meta-language in which simulations are written.

The usage of a special meta-language and an automatic compiler has several advantages over writing a big monolithic program or a set of library functions in C, Fortran, or another general-purpose programming language. The meta-language is more *powerful*; specifications are much simpler to write and easier to read when the syntax of the specification language reflects the problem domain. For example, the geometry of beamlines would be much more complex if it were specified in C code with static arrays and pointers. The compiler can also take care of the low-level details of interfacing the various parts of the specification with the underlying C implementation language and

each other. This way, users do not need to know about McXtrace internals to write new component or beamline definitions, and even if those internals change in later versions of McXtrace, existing definitions can be used without modification.

The McXtrace system also utilizes the meta-language to let the McXtrace compiler generate as much code as possible automatically, letting the compiler handle some of the things that would otherwise be the task of the user/programmer. *Correctness* is improved by having a well-tested compiler generate code that would otherwise need to be specially written and debugged by the user for every beamline or component. *Efficiency* is also improved by letting the compiler optimize the generated code in ways that would be time-consuming or difficult for humans to do. Furthermore, the compiler can generate several different simulations from the same specification, for example to optimize the simulations in different ways, to generate a simulation that graphically displays x-ray trajectories, and possibly other things in the future that were not even considered when the original instrument specification was written.

The design of McXtrace makes it well suited for doing “what if...” types of simulations. Once an instrument has been defined, questions such as “what if a slit was inserted”, “what if a focusing monochromator was used instead of a flat one”, “what if the sample was offset 0.2 mm from the center of the axis” and so on are easy to answer. Within minutes the beamline definition can be modified and a new simulation program generated. It also makes it simple to debug new components. A test beamline definition may be written containing a source, the component to be tested, and whatever monitors are useful, and the component can be thoroughly tested before being used in a complex simulation with many different components.

The McXtrace system is based on ANSI-C, making it both efficient and portable. The meta-language allows the user to embed arbitrary C code in the specifications. *Flexibility* is thus ensured since the full power of the C language is available if needed.

1.4. Overview

The McXtrace system documentation consists of the following major parts:

- A short list of new features introduced in this McXtrace release appears in chapter 2
- Chapter 3 explains how to obtain, compile and install the McXtrace compiler, associated files and supportive software
- Chapter 4 concerns Monte Carlo techniques and simulation strategies in general
- Chapter 5 includes a brief introduction to the McXtrace system (section 5.3) on running the compiler to produce simulations. section 5.4 explains how to run the generated simulations. Running McXtrace on parallel computers requires special attention and is discussed in section 5.7. A number of front-end programs are used to run the simulations and to aid in the data collection and analysis of the results. These user interfaces are described in section 5.5.

- The McXtrace meta-language is described in chapter 6. This chapter also describes a set of library functions and definitions that aid in the writing of simulations. See appendix B for more details.
- The McXtrace component library contains a collection of well-tested, as well as user contributed, beam components that can be used in simulations. The McXtrace component library is documented in a separate manual and on the McXtrace web-page [Mcx], but a short overview of these components is given in chapter 7 of the Manual.

A list of library calls that may be used in component definitions appears in appendix B, and an explanation of the McXtrace terminology can be found in appendix C of the Manual. Plans for future extensions are as a rule presented on the McXtrace web-page [Mcx].

2. New features in McXtrace 3.8

McXtrace is an ongoing evolving project with features being added frequently. While we strive to test it's features thoroughly, bugs are inevitable. Bugs are generally reported using the user-mailing list: `mcxtrace-users@mcxtrace.org` and subsequently (after initial triage) tracked using the McXtrace Trac system [Mcc] (shared with its sister project McStas). We will not present here an extensive list of improvements and corrections, and we let the reader refer to this bug reporting service for details. Only important changes are indicated here. Of course, we can not guarantee that the software is bullet proof, but we do our best to correct bugs, when they are reported.

The main focus of the 1.2 release has been to improved stability and fixing bug, rather than new developments.

2.1. Kernel

An important update has been made to the approach of negative propagation lengths. Instead of implicitly absorbing photons these are now generally restored. In many cases the previous behaviour casued confusion and counter-inutitive operation, in particular regarding mutually exclusive monitors with the flag `restore_xray` set.

2.2. Run-time

New intersection routines include `ellipsoid_intersect` and `sphere_intersect`.

2.3. Components and Library

We here list the new and updated components (found in the McXtrace `lib` directory) which are detailed in the *Component manual*. For an overview see the *Component Overview* of the *User Manual*(This Document).

2.3.1. New components

Sources

We have revised the following source models to make them work as conherently as possible while retaining the backwards compatibility.

Source_pt Point source.

Source_flat Flat surface uniform source

Source_div Flat surface uniform source with divergence distribution

Source_gaussian Gaussian crossection source approximating a Bending Magnet

Furthermore we now also supply an experimental model of a bending magnet **Bending_magnet**. The following experimental components have been set up to facilitate interfacing with SPECTRA, Simplex, and GENESIS 1.3. In general they take the output of the relevant external program to get a phase space distribution of photons from which McXtrace samples rays to trace.

Source_genesis Reads the output of a GENESIS 1.3 simulation. Useful for FEL-simulations.

Source_spectra Reads the output of a SPECTRA simulation. Useful for Synchrotron simulations.

Source_simplex Reads the output of a Simplex simulation. Useful for FEL simulations.

Samples

Single_crystal Now has support for wavelength dependent absorption.

Molecule_2state Also includes absorption support.

Molecule_2state Option for supplying a q-parametrized scattering amplitude curve. This is for instance useful to add the effect of a well known solvent (e.g. Water) to a simulation.

SAXS A whole set of SAXS-related samples is now available for various cases.

Optics

Filter Now has the option of taking any shape (through an .off or .ply-file).

Filter Added a refraction-option.

Multilayer_elliptic Elliptical multilayer mirror. This component now has the option of using a analytical kinematical approximation to compute reflectivity as opposed to supplying a datafile. This is faster, but often less accurate.

Lens_parab_* The lenses now behave in a similar manner wrt. parameter naming etc., also fixes to an error in the absorption computation. Note that the lens version will be merged in the next release (see the component manual).

Mirror_elliptic Elliptical shape mirror. Major geometry bug-fixes. Is scheduled to be merged with **Mirror_curved**.

Mirror_parabolic Parabolic shape mirror. Major geometry bug-fixes. Is scheduled to be merged with **Mirror_curved**.

Mirror_curved Cylindrical mirror. Fixed a bug which prevented its use as an azimuthal focusing mirror, with sideways incidence.

Chopper_simple Optional random jitter was added.

Mask A component that takes an image file as input, which is used to mask the beam. For instance to examine limited resolution effects.

Monitors

TOF_monitor New Intensity vs. time of flight monitor. Useful for time-resolved studies with pulsed sources.

2.3.2. Example instruments

The following beamline models have been added (in addition to unit test models that test specific components):

XFEL_SPB A rough model of the SPB beamline at the European XFEL.

MAXII_711 A model of the 711 powder diffraction beamline at Maxlab in Lund, Sweden.

MAXII_811 Model of the 811 surface diffraction and EXAFS beamline at Maxlab in Lund, Sweden.

2.4. Tools, installation

2.4.1. Selected Tool features

- standard FreeBSD port
- Possibility to run MPI or grid simulations by default from mxgui.
- We provide syntax-highlighting setup files for emacs, vim and gedit editors.

2.4.2. Warnings

WARNING: The 'dash' shell which is used as /bin/sh on some Linux system makes the 'Cancel' and 'Update' buttons fail in mxgui. Solutions are:

- a) If your system is a Debian or Ubuntu, please dpkg-reconfigure dash and say 'no' to install dash as /bin/sh
- b) If you run another Linux with /bin/sh being dash, please install bash and manually change the /bin/sh link to point at bash.

3. Installing McXtrace

Up to date information on installation procedures on the various supported platforms are available under the installation heading on the McXtrace project webpage: <http://www.mcxtrace.org>

3.0.1. Platform support

McXtrace is a multiplatform effort. The team policy is to supply native style installation packages for:

Mac OS X The aim is to supply installation packages for the 3 latest releases.

Windows We make packages for system supported by Microsoft.

Linux .deb based distributions.

Linux .rpm based distributions.

FreeBSD Through the ports system.

Plus probably any UNIX/POSIX type environment with a bit of effort, using the source distribution of McXtrace.

The team will be happy to make package builds for other types of systems on request. Please write to the user mailing list mcxtrace-users@mcxtrace.org to request a special build.

4. Monte Carlo Techniques and simulation strategy

This chapter explains the simulation strategy and the Monte Carlo techniques used in McXtrace. We first explain the concept of the x-ray weight factor, and discuss the statistical errors in dealing with sums of x-ray weights. Secondly, we give an expression for how the weight factor transforms under a Monte Carlo choice and specialize this to the concept of direction focusing. Finally, we present a way of generating random numbers with arbitrary distributions. More details are available in the Appendix concerning random numbers in the User manual.

4.1. X-ray simulations

X-ray scattering beamlines are built as a series of optical elements. Each of these elements modifies the beam characteristics (e.g. divergence, wavelength spread, spatial and temporal distributions) in a way which, for simple x-ray beam configurations, may be modelled with analytical methods.

However, real x-ray beamlines consist of a large number of optical elements, and this brings additional complexity by introducing strong correlations between x-ray beam parameters like divergence and position - which is the basis of the acceptance diagram method - but also wavelength and time. The usual analytical methods, such as phase-space theory, then reach their limit of validity in the description of the resulting effects.

In order to cope with this difficulty, Monte Carlo (MC) methods (for a general review, see Ref. [Jam80]) may be applied to the simulation of x-ray beamlines. The use of probability is commonplace in the description of microscopic physical processes. Integrating these events (absorption, scattering, reflection, ...) over the x-ray trajectories results in an estimation of measurable quantities characterizing the beamline. Moreover, using variance reduction (importance sampling) where possible, reduces the computation time and gives better accuracy.

Implementations of the MC method for X-ray beamlines already exist, most notable is probably *SHADOW*[WCC94], originally developed by the late Franco Cerrina and coworkers, now developed further by M. Sanchez Del Rio at the ESRF[Rio+11][Sha]. Other implementations of the same concept are *RAY*[Sch08] from BESSY and *Xtrace*[Bau+07]. hosted at ANKA

4.1.1. Monte Carlo ray tracing simulations

Mathematically, the Monte-Carlo method is an application of the law of large numbers [Jam80; GRR92]. Let $f(u)$ be a finite continuous integrable function of parameter u for which an integral estimate is desirable. The discrete statistical mean value of f (computed as a series) in the uniformly sampled interval $a < u < b$ converges to the mathematical mean value of f over the same interval.

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1, a \leq u_i \leq b}^n f(u_i) = \frac{1}{b-a} \int_a^b f(u) du \quad (4.1)$$

In the case where the u_i values are regularly sampled, we come to the well known midpoint integration rule. In the case where the u_i values are randomly (but uniformly) sampled, this is the Monte-Carlo integration technique. As random generators are not perfect, we rather talk about *quasi*-Monte-Carlo technique. We encourage the reader to refer to James [Jam80] for a detailed review on the Monte-Carlo method.

4.2. The x-ray weight

A totally realistic semi-classical simulation will require that each x-ray is at any time either present or lost. On many beamlines the sheer abundance of x-ray photons makes it impractical to trace each and every photon from the source. This is particularly the case at XFELs. Additionally, only a very small fraction of the initial x-rays will ever be detected, and simulations of this kind will therefore waste much time in dealing with x-rays that never hit the detector.

A way of dealing with these issues and speed up calculations is to introduce a x-ray "weight factor" for each simulated ray and to adjust this weight according to the path of the ray. If *e.g.* the reflectivity of a certain optical component is 10%, and only reflected x-rays are considered later in the simulations, the x-ray weight will be multiplied by 0.10 when passing this component, but every x-ray is allowed to reflect in the component. In contrast, the totally realistic simulation of the component would require on average ten incoming x-rays for each reflected one.

Let the initial x-ray weight be p_0 and let us denote the weight multiplication factor in the j 'th component by π_j . The resulting weight factor for the x-ray ray after passage of the whole beamline becomes the product of all contributions

$$p = p_n = p_0 \prod_{j=1}^n \pi_j. \quad (4.2)$$

Each adjustment factor should be $0 < \pi_j < 1$, except in special circumstances, so that total flux can only decrease through the simulation. For convenience, the value of p is updated (within each component) during the simulation.

Simulation by weight adjustment is performed whenever possible. This includes

- Transmission through filters and windows.

- Reflection from monochromator (and analyser) crystals with finite reflectivity and mosaicity.
- Reflections from mirrors.
- Passage of a continuous beam through a chopper.
- Scattering from all types of samples.

4.2.1. Statistical errors of non-integer counts

In a typical simulation, the result will consist of a count of x-ray histories ("rays") with different weights. The sum of these weights is an estimate of the mean number of x-rays hitting the monitor (or detector) per second in a "real" experiment. One may write the counting result as

$$I = \sum_i p_i = N\bar{p}, \quad (4.3)$$

where N is the number of rays hitting the detector and the horizontal bar denotes averaging. By performing the weight transformations, the (statistical) mean value of I is unchanged. However, N will in general be enhanced, and this will improve the accuracy of the simulation.

To give an estimate of the statistical error, we proceed as follows: Let us first for simplicity assume that all the counted x-ray weights are almost equal, $p_i \approx \bar{p}$, and that we observe a large number of x-rays, $N \geq 10$. Then N almost follows a normal distribution with the uncertainty $\sigma(N) = \sqrt{N}$ ¹. Hence, the statistical uncertainty of the observed intensity becomes

$$\sigma(I) = \sqrt{N}\bar{p} = I/\sqrt{N}, \quad (4.4)$$

as is used in real x-ray experiments (where $\bar{p} \equiv 1$). For a better approximation we return to Eq. (4.3). Allowing variations in both N and $\bar{p}$, we calculate the variance of the resulting intensity, assuming that the two variables are independent:

$$\sigma^2(I) = \sigma^2(N)\bar{p}^2 + N^2\sigma^2(\bar{p}). \quad (4.5)$$

Assuming as before that N follows a normal distribution, we reach $\sigma^2(N)\bar{p}^2 = N\bar{p}^2$. Further, assuming that the individual weights, p_i , follow a Gaussian distribution (which in some cases is far from the truth) we have $N^2\sigma^2(\bar{p}) = \sigma^2(\sum_i p_i) = N\sigma^2(p_i)$ and reach

$$\sigma^2(I) = N(\bar{p}^2 + \sigma^2(p_i)). \quad (4.6)$$

The statistical variance of the p_i 's is estimated by $\sigma^2(p_i) \approx (\sum_i p_i^2 - N\bar{p}^2)/(N-1)$. The resulting variance then reads

$$\sigma^2(I) = \frac{N}{N-1} \left(\sum_i p_i^2 - \bar{p}^2 \right). \quad (4.7)$$

¹This is not correct in a situation where the detector counts a large fraction of the x-rays in the simulation, but we will neglect that for now.

For almost any positive value of N , this is very well approximated by the simple expression

$$\sigma^2(I) \approx \sum_i p_i^2. \quad (4.8)$$

As a consistency check, we note that for all p_i equal, this reduces to eq. (4.4)

In order to compute the intensities and uncertainties, the detector components in McXtrace will keep track of $N = \sum_i p_i^0$, $I = \sum_i p_i^1$, and $M_2 = \sum_i p_i^2$.

4.3. Weight factor transformations during a Monte Carlo choice

When a Monte Carlo choice must be performed, *e.g.* when the initial energy and direction of the x-ray ray is decided at the source, it is important to adjust the x-ray weight so that the combined effect of x-ray weight change and Monte Carlo probability of making this particular choice equals the actual physical properties we like to model.

Let us follow up on the simple example of transmission. The probability of transmitting the real x-ray is P , but we make the Monte Carlo choice of transmitting the x-ray every time: $f_{\text{MC}} = 1$. This must be reflected on the choice of weight multiplier π_j given by the master equation. In the “real” semi-classical world, there is a distribution (probability density) for the x-rays in the six dimensional (energy, direction, position) space of $\Pi(E, \mathbf{\Omega}, \mathbf{r}) = dP/(dEd\mathbf{\Omega}d^3\mathbf{r})$ depending upon the source type and its parameters (such as gap, period, field strength etc. for an undulator). In the Monte Carlo simulations, the six coordinates are for efficiency reasons in general picked from another distribution: $f_{\text{MC}}(E, \mathbf{\Omega}, \mathbf{r}) \neq \Pi(E, \mathbf{\Omega}, \mathbf{r})$, since one would *e.g.* often generate only x-rays within a certain parameter interval. However, we must then require that the weights are adjusted by a factor π_j (in this case: $j = 1$) so that

$$f_{\text{MC}}\pi_j = P. \quad (4.9)$$

This probability rule is general, and holds also if, *e.g.*, it is decided to transmit only half of the rays ($f_{\text{MC}} = 0.5$). An important different example is elastic scattering from a powder sample, where the Monte-Carlo choices are the particular powder line to scatter from, the scattering position within the sample and the final x-ray direction within the Debye-Scherrer cone.

4.3.1. Direction focusing

An important application of weight transformation is direction focusing. Assume that the sample scatters the x-rays in many directions. In general, only x-rays in some of these directions will stand any chance of being detected. These directions we call the *interesting directions*. The idea in focusing is to avoid wasting computation time on x-rays scattered in the other directions. This trick is an instance of what in Monte Carlo terminology is known as *importance sampling*.

If *e.g.* a sample scatters isotropically over the whole 4π solid angle, and all interesting directions are known to be contained within a certain solid angle interval $\Delta\Omega$, only these solid angles are used for the Monte Carlo choice of scattering direction. According to Eq. (4.9), the weight factor will then have to be changed by the amount $\pi_j = |\Delta\Omega|/(4\pi)$. One thus ensures that the mean simulated intensity is unchanged during a "correct" direction focusing, while a too narrow focusing will result in a lower (*i.e.* wrong) intensity, since we cut x-rays that should have reached the final detector.

Figure 4.1.: Illustration of the effect of direction focusing in McXtrace. Weights of x-rays emitted into a certain solid angle are scaled down by the full unit sphere area.

4.4. Stratified sampling

One particular efficiency improvement technique is the so-called *stratified sampling*. It consists in partitioning the event distributions in representative sub-spaces, which are then all sampled individually. The advantage is that we are then sure that each sub-space is well represented in the final integrals. This means that instead of shooting N events, we define D partitions and shoot $r = N/D$ events in each partition. We may define partitions so that they represent 'interesting' distributions, *e.g.* from events scattered on a monochromator or a sample. The sum of partitions should equal the total space integrated by the Monte Carlo method, and each partition must be sampled randomly.

In the case of McXtrace, the stratified sampling is used when repeating events, *i.e.* when using the SPLIT keyword in the TRACE section on beamline descriptions. We emphasize here that the number of repetitions r should not exceed the dimensionality of the Monte Carlo integration space (which is $d = 10$ for x-ray events) and the dimen-

Records	Accuracy
10^3	10 %
10^4	2.5 %
10^5	1 %
10^6	0.25 %
10^7	0.05 %

Table 4.1.: Accuracy estimate as a function of the number of statistical events used to estimate an integral with McXtrace.

sionality of the partition spaces, i.e. the number of random generators following the stratified sampling location in the beamline.

4.5. Accuracy of Monte Carlo simulations

When running a Monte Carlo, the meaningful quantities are obtained by integrating random events into a single value (e.g. flux), or onto an histogram grid. The theory [Jam80] shows that the accuracy of these estimates is a function of the space dimension d and the number of events N . For large numbers N , the central limit theorem provides an estimate of the relative error as $1/\sqrt{N}$. However, the exact expression depends on the random distributions.

McXtrace uses a space with $d = 12$ parameters to describe x-rays (position, wavevector, weight, polarisation, phase, time). We show in Table 4.1 a rough estimate of the accuracy on integrals as a function of the number of records reaching the integration point. This stands both for integrated flux, as well as for histogram bins - for which the number of events per bin should be used for N .

5. Running McXtrace

This chapter describes usage of the McXtrace simulation package. In case of problems regarding installation or usage, the McXtrace mailing list [Mcx] or the authors should be contacted.

Performing a simulation using McXtrace can be divided into the following steps/elements

- To use McXtrace, an instrument definition file describing the beamline to be simulated must be written. Alternatively, an example instrument file can be obtained from the `examples/` directory in the distribution or from another source.
- The input files (instrument and component files) are written in the McXtrace meta-language and are edited either by using your favorite editor or by using the built-in editor of the graphical user interface (`mxgui`).
- Next, the McXtrace compiler `mcxtrace` is invoked to translate the instrument and component files into a C program. The program `mcxtrace` itself is written in C, using the parser *flex* and the compiler compiler *bison*.
- The resulting C program can then be compiled with a C compiler and run in combination with various front-end programs for example to present the intensity at the detector as a motor position is varied.
- The output data may be analyzed and visualized in the same way as regular experiments by using the data handling and visualization tools in McXtrace. As of McXtrace 3.x, these front-ends (`mxplot`, `mxdisplay`, ...) are all implemented in Python, using `matplotlib`, `pyqtgraph` and browser/HTML (D3.js) back-ends, see section 5.5. Further data output formats including NeXus are available, see section 5.6.

5.1. Installation and updates

For installation notes, see the web site [Mcx]. In case of problems, write the support mailing list, or contact the authors.

Installation via conda-forge (recommended)

The recommended installation method for all supported platforms—Linux, macOS, and Windows—is via the `conda-forge` channel. Once a conda-compatible environment manager such as Miniforge or Mambaforge is available, McXtrace can be installed into a fresh conda environment:

```
conda create -n mcxtrace -c conda-forge mcxtrace
conda activate mcxtrace
mxgui
```

On Windows a dedicated `mcxtrace-conda` batch script is provided by the installer. After it completes, use the `mcxtrace-shell` desktop shortcut and issue `mxgui` to start the graphical interface.

For full platform-specific installation instructions, including Linux package management and macOS options, see:

<https://github.com/mccode-dev/McCode/tree/main/INSTALL-McXtrace>

5.1.1. Important note for Windows users

It is a known problem that some of the McXtrace tools do not support filenames / directories with spaces. We recommend avoiding spaces in the paths used for McXtrace work directories and instrument files. As of McXtrace 3.x, all tools (`mxgui`, `mxrun`, `mxplot`, `mxdisplay`, ...) are pure Python and are bundled with the `conda-forge` package, so no separate Perl installation is required on any platform, including Windows.

5.1.2. New releases of McXtrace

Releases of new versions of a software package can today be carried out more or less continuously. However, users do not update their software on a daily basis, and as a compromise we have adopted the following policy of McXtrace.

- The versions 3.8.x will possibly contain bug fixes and minor new functionality. A new manual will, however, not be released and the modifications are documented on the McXtrace web-page. The extensions of the forthcoming version 3.8.x are also listed on the web, and new versions may be released quite frequently when it is requested by the user community.

5.2. Brief introduction to the graphical user interface

This section gives an ultra-brief overview of how to use McXtrace once it has been properly installed. It is intended for those who do not read manuals if they can avoid it. For details on the different steps, see the following sections.

To start the graphical user interface of McXtrace, run the `mxgui` command which will open a window with a number of menus, see figure 5.1. To load an instrument, select “New from Template” and open one of the template/example instruments (see chapter ?? for a tour). Next, check that the current plotting backend setting (“Preferences” in the **File** menu, or the `--autoplottter` option of `mxrun`) corresponds to your system setup:

- by editing the user configuration file, see `mxrun --edit-user-config`,
- or by setting the `MCXTRACE_FORMAT` environment variable.

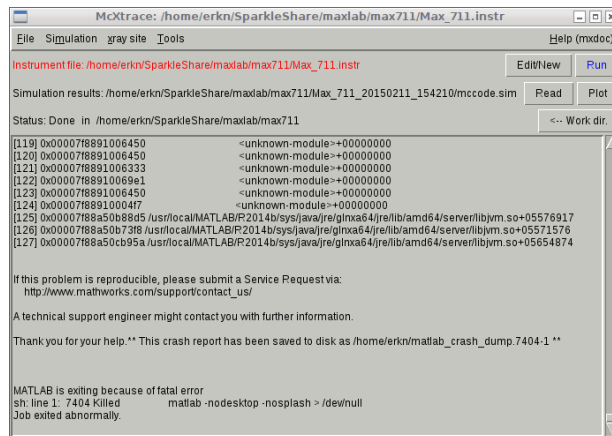

Figure 5.1.: The graphical user interface `mxgui`.

Next, select “Run simulation” from the “Simulation” menu. The `McXtrace` compiler `mcxtrace` will translate the definition into an executable program. Then `mxgui` will pop up a dialog window. Enter suitable values for the instrument parameters, check the “Plot results” option, and select “Start”. The simulation will run, and when it finishes after a while the results will be plotted in a window, using one of the Python plotting back-ends (`matplotlib`, `pyqtgraph` or an HTML/browser view), see section 5.5.5. For other options, execute `mxplot --help` to get help.

To visualize or debug the simulation graphically, repeat the steps but check the “Trace” option instead of the “Simulate” option. A window will pop up showing a sketch of the instrument, drawn by the `mxdisplay` front-end (section 5.5.4), again using one of the `matplotlib`, `pyqtgraph` or `webGL` back-ends.

For more technical details, read on from section 5.3.

5.3. Running the instrument compiler

This section describes how to run the `McXtrace` compiler `mcxtrace` manually. Often, it will be more convenient to use the front-end program `mxgui` (section 5.5.1) or `mxrun` (section 5.5.2), which run the compilation and the simulations automatically.

Upon a command of the form

```
mcxtrace name.instr
```

the compiler `mcxtrace` will read the instrument definition `name.instr`, written in the `McXtrace` meta-language, and translate it into a Monte Carlo simulation program in the programming language C. The output is by default written to a file in the current directory with the same name as the instrument file, but with extension `.c` rather than `.instr`. This can be overridden using the `-o` option as follows:

```
mcxtrace -o code.c name.instr
```

which gives the output in the file `code.c`. A single dash ‘-’ may be used for both input and output filename to represent standard input and standard output, respectively.

5.3.1. Code generation options

By default, the code generated by `mcxtrace` is ISO-C with some extensions (currently the only extension is the creation of new directories, which is not possible in pure ISO-C). The use of extensions may be disabled with the `-p` or `--portable` option. With this option, the output is strictly ISO-C compliant, at the cost of some slight reduction in capabilities.

The `-t` or `--trace` option puts special “trace” code in the output. This code makes it possible to get a complete trace of the path of every x-ray through the instrument, as well as the position and orientation of every component. This option is mainly used with the `mxdisplay` front-end as described in section 5.5.4.

The code generation options can also be controlled by using preprocessor macros in the C compiler, without the need to re-run `mcxtrace`. If the preprocessor macro `MC_PORTABLE` is defined, the same result is obtained as with the `--portable` option. The effect of the `--trace` option may be obtained by defining the `MC_TRACE_ENABLED` macro. Most Unix-like C compilers allow preprocessor macros to be defined using the `-D` option, e.g.

```
cc -DMC_TRACE_ENABLED -DMC_PORTABLE ...
```

Finally, the `--verbose` option will list the components and libraries being included in the instrument.

Alternative code generator: `mccode-antlr`

An alternative code generator, `mcxtrace-antlr`, is available alongside the classic `mcxtrace` compiler, as part of the `mccode-antlr` package. It is built on the ANTLR parser framework rather than the traditional `lex/yacc` toolchain, is implemented primarily in Python, and is a candidate replacement for the default generator in future releases.

Select it on a per-run basis with the `--cogen` flag:

```
mxrun --cogen=mcxtrace-antlr MyInstrument.instr -n 1e8
```

The active code generator can also be set permanently by editing the `MCCOGEN` field in `mccode_config.json`. This file is accessible from the command line with:

```
mxrun --edit-user-config
```

or via the *Save/Edit configuration* dialogue inside `mxgui`.

As with the equivalent `mcstas-antlr` generator for McStas, consult the `mccode-antlr` project documentation for the current status of GPU/OpenACC support, which may lag behind that of the classic generator.

5.3.2. Specifying the location of files

The McXtrace compiler `mcxtrace` needs to be able to find various files during compilation, some explicitly requested by the user (such as component definitions and files referenced by `%include`), and some used internally to generate the simulation executable.

McXtrace looks for these files in three places: first in the current directory, then in a list of directories given by the user, and finally in a special McXtrace directory. Usually, the user will not need to worry about this as `mcxtrace` will automatically find the required files. But if users build their own component library in a separate directory or if `mcxtrace` is installed in an unusual way, it will be necessary to tell the compiler where to look for the files.

The location of the special McXtrace directory is set when `mcxtrace` is compiled. It defaults to a location under the active `conda-forge` environment, but it can be changed to something else, see the installation instructions for details.

The location can be overridden by setting the environment variable `MCXTRACE`:

```
setenv MCXTRACE /home/joe/mcxtrace
```

for `csh/tcsh` users, or

```
export MCXTRACE=/home/joe/mcxtrace
```

for `bash/Bourne` shell users. Windows users should define `MCXTRACE` from the menu 'Start/Settings/Control Panel/System/Advanced/Environment Variables' by creating `MCXTRACE` with the value `C:\mcxtrace\lib`

To make `mcxtrace` search additional directories for component definitions and include files, use the `-I` switch:

```
1 mcxtrace -I/home/joe/components -I/home/joe/xray/include name.instr
```

Multiple `-I` options can be given, as shown.

5.3.3. Embedding the generated simulations in other programs

By default, `mcxtrace` will generate a stand-alone C program, which is what is needed in most cases. However, for advanced usage, such as embedding the generated simulation in another program or even including two or more simulations in the same program, a stand-alone program is not appropriate. For such usage, `mcxtrace` provides the following options:

- `--no-main` This option makes `mcxtrace` omit the `main()` function in the generated simulation program. The user must then arrange for the function `mcxtrace_main()` to be called in some way.
- `--no-runtime` Normally, the generated simulation program contains all the run-time C code necessary for declaring functions, variables, etc. used during the simulation. This option makes `mcxtrace` omit the run-time code from the generated simulation program, and the user must then explicitly link with the file `mcxtrace-r.c` as well as other shared libraries from the McXtrace distribution.

Users that need these options are encouraged to contact the authors for further help.

5.3.4. Running the C compiler

After the source code for the simulation program has been generated with `mcxtrace`, it must be compiled with the C compiler to produce an executable. Since the generated C code obeys the ISO-C standard, it should be easy to compile it using any ISO-C (or C++) compiler. *E.g.* a typical Unix-style command would be

```
1 cc -O -o name.out name.c -lm
```

The McXtrace team recommends these compiler alternatives for the Intel (and AMD) hardware architectures:

- A** `gcc` which is a very portable, open source, ISO-C compatible c compiler, available for most platforms. For Linux it is usually part of your distribution, and for Windows and Mac OS X a version of `gcc` is bundled with the `conda-forge` package.
- B** `icc` or the Intel c compiler is available for Linux, Mac OS and Windows systems and is a commercial software product. Generally, simulations run with the Intel compiler are **a factor of 2 faster** than the identical simulation run using `gcc`. To use `icc` with McXtrace on Linux or Mac OS X, set the environment variables

```
– MCXTRACE_CC=icc
– MCXTRACE_CFLAGS="-g -O2 -wd177,266,1011,181"
```

To use `icc` with MPI on Unix system (see Section 5.7) installations, it seems that *editing* the `mpicc` shell script and setting the `CC` variable to "`icc`" is the only requirement! On Windows, the Intel c compiler is '`icl`', not '`icc`' and has a dependency for Microsoft Visual C++. If you have both these softwares available, running McXtrace with the Intel compiler should be possible (currently untested by the McXtrace developer team).

The `-O` option typically enables the optimization phase of the compiler, which can make quite a difference in speed of `mcxtrace`-generated simulations. The `-o name.out` sets the name of the generated executable. The `-lm` options is needed on many systems to link in the math runtime library (like the `cos()` and `sin()` functions).

Monte Carlo simulations are computationally intensive, and it is often desirable to have them run as fast as possible. Some success can be obtained by adjusting the compiler optimization options.

A general comment about optimization is that it should be used cautiously, checking that the results are not significantly affected. Even worse, compiler optimizations are notoriously buggy; `mcxtrace` actually puts an effort into making the task of the C compiler easier, by in-lining code and using variables in an efficient way. As a result, McXtrace simulations generally run quite fast, often fast enough that further optimizations are not worthwhile. Also, optimizations are highly time and memory consuming during compilation, and thus may fail when dealing with large instrument descriptions (e.g. more

that 100 elements). The compilation process is simplified when using components of the library making use of shared libraries (see **SHARE** keyword in the Component Manual). Refer to section 5.4.4 for other optimization methods.

5.4. Running the simulations

Once the simulation program has been generated by the McXtrace compiler **mcxtrace** and an executable has been obtained with the C compiler, the simulation can be run in various ways.

Simple McXtrace options

In this section, the most common simulation parameters are discussed. For a full list, please consult Tables 5.1 and 5.2.

The simplest way is to run it directly from the command line or shell:

```
1 ./name.out
```

Note the leading “.”, which is needed if the current directory is not in the path searched by the shell. When used in this way, the simulation will prompt for the values of any instrument parameters such as motor positions, and then run the simulation. Default instrument parameter values (see section 6.3), if any, will be indicated and entered when hitting the **Return** key. This way of running McXtrace will only give data for one instrument setting, which is normally sufficient for *e.g.* imaging or SAXS instruments, but not for *e.g.* instruments where a scan over various instrument settings is required. Often the simulation will be run using one of several available front-ends, as described in the next section. These front-ends help manage output from the potentially many detectors in the instruments, as well as running the simulation for each data point in a scan.

The generated simulations accept a number of options and arguments. The full list can be obtained using the **--help** option:

```
1 ./name.out --help
```

The values of instrument parameters may be specified as arguments using the syntax *name=val*. For example

```
1 ./MAXII.711.out R=90
```

The number of x-ray histories to simulate may be set using the **--ncount** or **-n** option, for example **--ncount=2e5**. The initial seed for the random number generator is by default chosen based on the current time so that it is different for each run. However, for debugging purposes it is sometimes convenient to use the same seed for several runs, so that the same sequence of random numbers is used each time. To achieve this, the random seed may be set using the **--seed** or **-s** option.

By default, McXtrace simulations write their results into several data files in the current directory, overwriting any previous files stored there. The **--dir=dir** or **-ddir**

option causes the files to be placed instead in a newly created directory *dir* (to prevent overwriting previous results an error message is given if the directory already exists). Alternatively, all output may be written to a single file *file* using the `--file=file` or `-f file` option (which should probably be avoided when saving in binary format, see below). If the *file* is given as `NULL`, the file name is automatically built from the instrument name and a time stamp. The default file name is `mccode` followed by appropriate extension.

The complete list of options and arguments accepted by McXtrace simulations appears in Tables 5.1 and 5.2.

5.4.1. Choosing an output data file format

Data files contain header lines with information about the simulation from which they originate. In case the data must be analyzed with programs that cannot read files with such headers, they may be turned off using the `--data-only` option (of the generated `<instr>.out` executable itself – do not confuse this with `mxrun`'s own `-a/--append` option, which appends a new simulation's data files to an existing output directory, see Table 5.1).

The format of the output files from McXtrace simulations is described in more detail in section 5.6. It may be chosen either with `--format=FORMAT` for each simulation or globally by setting the `MCXTRACE_FORMAT` environment variable. The available format list is obtained using the `name.out --help` option. McXtrace can presently generate data in the McXtrace/McCode text format or the NeXus format (see section 5.6.2).

It is also possible to read and write x-ray event lists using the `MCPL_input/MCPL_output` components (see the Component Manual), which use the portable, compressed, multi-code MCPL event format rather than any particular code's native event format. This is the recommended way to exchange x-ray/neutron events between McXtrace/McStas and other Monte Carlo codes.

Additionally, adding the `raw` keyword to the `FORMAT` will produce raw $[N, p, p^2]$ data sets instead of $[N, p, \sigma]$ (see Section 4.2.1). The former representation is fully additive, and thus enables to add results from separate simulations. Other acceptable format modifiers are `transpose` to transpose data matrices and `append` to concatenate data to existing files.

5.4.2. Basic import and plot of results

The previous example will result in a `mccode.sim` index file plus one data file per monitor in the output directory. These are plain-text McXtrace/McCode format files (see section 5.6) that can be read directly with NumPy (`numpy.loadtxt`) or any other language capable of reading text tables, or, more conveniently, with the `mxplot` front-end and its underlying data loader (`mccodelib.mcplotloader`), see section 5.5.5.

When using the HTML plotting back-end (`mxplot-html`), simulation results are rendered as an interactive, self-contained web page (using D3.js) rather than being saved as static images.

The full, up-to-date list of options accepted by `mxrun` and by the generated `<instr>.out` executable is given in Tables 5.1 and 5.2 below; run `mxrun --help` for the same information at the command line.

Table 5.1.: `mxrun`-specific options (compilation, scanning, optimisation, MPI/OpenACC).

Option	Description
<code>-c</code> <code>--force-compile</code>	force rebuilding of instrument
<code>--cogen <i>cogen</i></code>	Choice of code-generator (implies <code>-c</code>)
<code>-C</code> <code>--c-lint</code>	Use c-linter (e.g. <code>cppcheck</code>) to lint the generated code. Configure linter via <code>mccode_config.json</code> . Implies <code>-c</code> and <code>-v</code> , but also NO simulation will be run.
<code>-I</code>	Append to McCode search path (implies <code>-c</code>)
<code>--D1 <i>D1</i></code>	Set extra <code>-D</code> args (implies <code>-c</code>)
<code>--D2 <i>D2</i></code>	Set extra <code>-D</code> args (implies <code>-c</code>)
<code>--D3 <i>D3</i></code>	Set extra <code>-D</code> args (implies <code>-c</code>)
<code>-p</code> <code>--param <i>FILE</i></code>	Read parameters from file <code>FILE</code>
<code>-N</code> <code>--numpoints <i>NP</i></code>	Set number of scan points
<code>--seeds <i>SEEDS</i></code>	Set range of seeds to scan (each must be: <code>SEED != 0</code>)
<code>-L</code> <code>--list</code>	Use a fixed list of points for linear scanning
<code>-M</code> <code>--multi</code>	Run a multi-dimensional scan
<code>--scan_split <i>scan_split</i></code>	Scan by parallelising steps as individual cpu threads. Initialise by number of wanted threads (e.g. your number of cores).
<code>--autoplot</code>	Open plotter on generated dataset
<code>--invcanvas</code>	Forward request for inverted canvas to plotter
<code>--autoplotter</code>	Specify the plotter used with <code>--autoplot</code>
<code>--embed</code>	Store copy of instrument file in output directory (<i>default: True</i>)
<code>--mpi <i>NB_CPU</i></code>	Spread simulation over <code>NB_CPU</code> machines using MPI
<code>--openacc</code>	parallelize using openacc
<code>--funnel</code>	funneling simulation flow, e.g. for mixed CPU/GPU
<code>--machines <i>machines</i></code>	Defines path of MPI machinefile to use in parallel mode

Option	Description
<code>--optimise-file <i>FILE</i></code>	Store scan results in <i>FILE</i> (defaults to: "mc-code.dat")
<code>--no-cflags</code>	Disable optimising compiler flags for faster compilation
<code>--no-main</code>	Do not generate a <code>main()</code> , e.g. for use with <code>mcstas2vitess.pl</code> . Implies <code>-c</code>
<code>--verbose</code>	Enable verbose output
<code>--write-user-config</code>	Generate a user config file
<code>--edit-user-config</code>	Generate and edit user config file in <code>EDITOR</code>
<code>--override-config <i>PATH</i></code>	Load config file from specific dir
<code>--optimize</code>	Optimize instrument variable parameters to maximize monitors
<code>--optimize-maxiter <i>optimize_maxiter</i></code>	Maximum number of optimization iterations to perform. Default=1000 (<i>default: 1000</i>)
<code>--optimize-tol <i>optimize_tol</i></code>	Tolerance for optimization termination. When <code>optimize-tol</code> is specified, the selected optimization algorithm sets some relevant solver-specific tolerance(s) equal to <code>optimize-tol</code>
<code>--optimize-method <i>optimize_method</i></code>	Optimization solver in [...] (default: [...]) You can use your custom method <code>method(fun, x0, args, **kwargs, **options)</code> . Please refer to scipy documentation for proper use of it: https://docs.scipy.org/doc/scipy/reference/generated/scipy.optimize
<code>--optimize-eval <i>optimize_eval</i></code>	Optimization expression to evaluate for each detector "d" structure. You may combine: "d.intensity" The detector intensity; "d.error" The detector intensity uncertainty; "d.values" An array with [intensity, error, counts]; "d.X0 d.Y0" Center of signal (1st moment); "d.dX d.dY" Width of signal (2nd moment). Default is "d.intensity". Examples are: "d.intensity/d.dX" and "d.intensity/d.dX/d.dY"
<code>--optimize-minimize</code>	Choose to minimize the monitors instead of maximize
<code>--optimize-monitor <i>optimize_monitor</i></code>	Name of a single monitor to optimize (default is to use all)
<code>--showcfg <i>ITEM</i></code>	Print selected cfg item and exit (paths are resolved and absolute). Allowed values are particle.

Table 5.2.: Instrument/simulation options (also accepted directly by the generated `<instr>.out` executable).

Option	Description
<code>-s</code> <code>--seed <i>SEED</i></code>	Set random seed (must be: <code>SEED != 0</code>)
<code>-n</code> <code>--ncount <i>COUNT</i></code>	Set number of particles to simulate (<i>default: 1000000</i>)
<code>-t</code> <code>--trace <i>trace</i></code>	Enable trace of particles through instrument (<i>default: 0</i>)
<code>--no-trace <i>notrace</i></code>	Disable trace of particles in instrument (combine with <code>-c</code>)
<code>-y</code> <code>--yes</code>	Assume any default parameter value in instrument
<code>-d</code> <code>--dir <i>DIR</i></code>	Put all data files in directory <code>DIR</code> . If unspecified <code>INSTRUMENT_TIMESTAMP</code> is used
<code>--dirprefix <i>dirprefix</i></code>	Put all data files in directory <code>PREFIX_TIMESTAMP</code>
<code>--dirsuffix <i>dirsuffix</i></code>	Put all data files in directory <code>INSTRUMENT_DIRSUFFIX</code>
<code>-a</code> <code>--append</code>	Append data files to those already in directory <code>DIR</code>
<code>--format <i>FORMAT</i></code>	Output data files using format <code>FORMAT</code> , usually <code>McCode</code> or <code>NeXus</code> (format list obtained from <code>jinstr;.out -h</code>) (<i>default: McCode</i>)
<code>--bufsiz <i>BUFSIZ</i></code>	Monitor <code>nD</code> list/buffer-size (defaults to [...])
<code>--vecsize <i>VECSIZE</i></code>	vector length in OpenACC parallel scenarios
<code>--numgangs <i>NUMGANGS</i></code>	number of 'gangs' in OpenACC parallel scenarios
<code>--gpu_innerloop <i>INNER-LOOP</i></code>	Maximum particles in an OpenACC kernel run. (If <code>INNERLOOP</code> is smaller than <code>ncount</code> we repeat)
<code>--no-output-files</code>	Do not write any data files
<code>-i</code> <code>--info</code>	Detailed instrument information
<code>--list-parameters</code>	Print the instrument parameters to standard out
<code>--meta-list</code>	Print all metadata defining component names
<code>--meta-defined</code>	Print metadata names for component, or indicate if component: name exists
<code>--meta-type</code>	Print metadata type for component: name
<code>--meta-data</code>	Print metadata for component: name
<code>-g</code> <code>--gravitation</code> <code>--gravity</code>	Enable gravitation for all trajectories

Option	Description
--IDF	Flag to attempt inclusion of XML-based IDF when <code>-format=NeXus</code> (format list obtained from <code>jinstr_i.out -h</code>)

5.4.3. Interacting with a running simulation

Once the simulation has started, it is possible, under Unix, Linux and Mac OS X systems, to interact with the on-going simulation. This feature is not available when using MPI parallelization.

McXtrace attaches a signal handler to the simulation process. In order to send a signal to the process, the process-id *pid* must be known. Users may look at their running processes with the Unix 'ps' command, or alternatively process managers like 'top' and 'gtop'. If a *file.out* simulation obtained from McXtrace is running, the process status command should output a line resembling

```
1 <user> 13277 7140 99 23:52 pts/2 00:00:13 file.out
```

where **user** is your Unix login. The *pid* is there '13277'.

Once known, it is possible to send one of the signals listed in Table 5.3 using the 'kill' unix command (or the functionalities of your process manager), e.g.

```
1 kill -USR2 13277
```

This will result in a message showing status (here 33 % achieved), as well as the position in the instrument of the current x-ray.

```
1 # McXtrace: [pid 13277] Signal 12 detected SIGUSR2 (Save simulation)
2 # Simulation: file (file.instr)
3 # Breakpoint: MyDetector (Trace) 33.37 % ( 333654.0/ 1000000.0)
4 # Date       : Wed May 7 00:00:52 2003
5 # McXtrace: Saving data and resume simulation (continue)
```

followed by the list of detector outputs (integrated counts and files). Finally, sending a `kill 13277` (which is equivalent to `kill -TERM 13277`) will end the simulation before the initial 'ncount' preset.

A typical usage example would be, for instance, to save data during a simulation, plot or analyze it, and decide to interrupt the simulation earlier if the desired statistics has been achieved. This may be done automatically using the **Progress_bar** component.

Whenever simulation data is generated before end (or the simulation is interrupted), the 'ratio' field of the monitored data will provide the level of achievement of the computation (for instance '3.33e+05/1e+06'). Intensities are then usually to be scaled accordingly by the user.

Additionally, any system error will result in similar messages, giving indication about the occurrence of the error (component and section). Whenever possible, the simulation will *try* to save the data before ending. Most errors appear when using a newly written component, in the INITIALIZE, TRACE or FINALLY sections. Memory errors usually

USR1	Request information (status)
USR2, HUP	Request information and performs an intermediate saving of all monitors (status and save). This triggers the execution of all SAVE sections (see the Component Manual).
INT, TERM	Save and exit before end (status)

Table 5.3.: Signals supported by McXtrace simulations.

show up when C pointers have not been allocated/unallocated before usage, whereas mathematical errors are found when, for instance, dividing by zero.

5.4.4. Optimizing simulation speed

There are various ways to speed up simulations

- Optimize the compilation of the instrument, as explained in section 5.3.4.
- Execute the simulation in parallel on a computer cluster using MPI, or simply across the cores of a single machine, as explained in section 5.7.
- Divide simulation into parts using a file for saving or generating x-ray events. In this way, a beamline section may be simulated only once, saving the x-ray events at its exit as a file, which is being read quickly by the second simulation part. Use the `MCPL_output` and `MCPL_input` components for this technique (see the Component Manual).
- Complex components usually take into account additional small effects in a simulation, but are much longer to execute. Thus, simple components should be preferred whenever possible, at least in the beginning of a simulation project.
- The `SPLIT` keyword may artificially repeat events reaching specified positions in the instrument. This is *very* efficient, but requires to cast random numbers in the course of the remaining propagation (e.g. at samples, crystals, ...). See section 6.4.7 for details.

A general comment about optimization is that it should be used cautiously, checking that the results are not significantly affected.

5.4.5. Optimizing instrument parameters

Often, the user may wish to optimize the parameters of a simulation, i.e. the best geometry of a given component, for example the optimal curvature of a focusing mirror.

The choice of the optimization routine, of the simulation quality value to optimize, the initial parameter guess and the simulation length all have a large influence on the results. The user is advised to be cautious when interpreting the optimization results.

Using the built-in --optimize mode

The McXtrace package comes with a built-in optimization mode to find instrument parameters that maximize (or minimize) the value of all, or some specified, monitors. As of McXtrace 3.x this is implemented in `mxrun` using the `scipy.optimize.minimize` family of solvers [Sci]. Available methods include `powell` (the default), `nelder-mead`, `cg`, `bfgs`, `newton-cg`, `l-bfgs-b`, `tnc`, `cobyla`, `slsqp`, `trust-constr`, `dogleg`, `trust-ncg`, `trust-exact` and `trust-krylov`; consult the SciPy documentation for the properties of each. As with any non-linear optimizer, results depend on the initial guess and the chosen method, and higher-dimensional problems (many free parameters) are not guaranteed to converge to a meaningful, global optimum.

When using `mxrun` (section 5.5.2), the optimization mode is set by using the `--optimize` flag, together with instrument parameter ranges specified exactly as for a scan, e.g. `param=min,max`. The solver is selected with `--optimize-method=METHOD`, the convergence tolerance with `--optimize-tol=TOL`, and the maximum number of iterations with `--optimize-maxiter=N`. By default all monitors are summed as the figure of merit; a single monitor may be targeted instead with `--optimize-monitor=NAME`, and `--optimize-minimize` inverts the sense of the search (minimize rather than maximize). For full control over the optimized quantity, use `--optimize-eval=EXPR` with an expression combining the fields of a detector structure `d` (`d.intensity`, `d.error`, `d.values`, `d.X0/d.Y0`, `d.dX/d.dY`), e.g. `--optimize-eval="d.intensity/d.dX"`. See Table 5.1 for the complete, up-to-date option list.

Example:

```
1 mxrun MAXII.711.instr --optimize --optimize-monitor=det R=1,200
```

From `mxgui` (section 5.5.1), one should choose the 'Optimization' execution mode (instead of the Simulation or Trace mode). Then specify the instrument parameters to optimize by indicating their variation range `param=min,max` just like parameter scans. Finally, run the simulation. The optimum set of parameters is then printed at the end of the simulation process. You may ask to maximize only a given monitor (instead of all) by selecting its component name in the Run Dialog.

The optimization search interval constrains the evolution of parameters. It should be chosen carefully. In particular it is safer for it to indeed contain a high signal domain, and be preferably symmetric with respect to that maximum.

5.5. Using simulation front-ends

McXtrace includes a number of front-end programs that extend the functionality of the simulations. A front-end program is an interface between the user and the simulations, running the simulations and presenting the output in various ways to the user.

The list of available McXtrace front-end programs is (see `mxdoc --tools`, or run any tool with `-h` for its specific help):

```
1 McXtrace Tools
2 mcxtrace          Main instrument compiler
```

```

3      mxrun          Instrument build and execution utility
4      mxgui          Graphical User Interface instrument builder
5      mxdoc          Component library documentation generator/viewer
6      mxplot         Simulation result viewer (default: pyqtgraph backend
7      )
8      mxplot-html    Simulation result viewer, in a web browser (D3.js)
9      mxplotdiff-html Difference plot between two simulation results, in a
10     browser
11     mxcoplot-html   Overlay (co-plot) of two simulation results' 1D
12     monitors
13     mxdisplay       Instrument geometry viewer (default: pyqtgraph
14     backend)
15     mxtest          Self-test / benchmark of the current McXtrace
16     installation
17     mxviewtest       Viewer for mxtest results, with mxplotdiff-html
18     comparisons
19     Each tool also exists in dedicated *-matplotlib, *-pyqtgraph, *-html,
20     *-webgl or *-webgl-classic variants where applicable, see sections
21     below.
22     DOC:             Please visit https://www.mcxtrace.org

```

5.5.1. The graphical user interface (mxgui)

The front-end `mxgui` provides a graphical user interface that interfaces the various parts of the McXtrace package. It may be started with the single command

```

1      mxgui

```

The `mxgui` program may optionally be given the name of the instrument file to use.

Dependencies: As of McXtrace 3.x, `mxgui` is a pure Python/Qt application (PyQt), bundled with the standard conda-forge McXtrace package; no separate Perl, Tk, or PGPLOT installation is required.

The menus

When the front-end is started the main window is opened (see figure 5.1). This window displays the output from compiling and running simulations, and contains a few menus and buttons for easy navigation. The main purpose of the front-end is to edit and compile instrument definitions, run the simulations, and visualize the results.

The **File** menu has the following features:

File/Open instrument selects the name of an instrument file to be used.

File/Edit current opens a simple editor window with McXtrace syntax highlighting for editing the current instrument definition. This function is also available from the **Edit** button to the right of the name of the instrument definition in the main window.

File/Spawn editor This starts the editor defined in the environment variable `VISUAL` or `EDITOR` on the current instrument file. It is also possible to start an external editor manually; in any case `mxgui` will recompile instrument definitions as necessary based on the modification dates of the files on the disk.

File/Compile instrument forces a recompile of the instrument definition, regardless of file dates. This is for example useful to pick up changes in component definitions, which the front-end will not notice automatically. This might also be required when choosing MPI and NeXus options.

File/Save log file saves the text in the window showing output of compilations and simulations into a file.

File/Clear output erases all text in the window showing output of compilations and simulations.

File/Preferences Opens the configuration dialog shown in figure 5.2. Several settings can be chosen here:

- Selection of the desired plotting/display backend (`pyqtgraph`, `matplotlib`, `html`, ...) for `mxplot` and `mxdisplay`.
- Choice of editor to use when editing instrument files.
- Automatic quotation of strings when inserting in the built-in editor.
- Possibility to *not* optimize when compiling the generated c-code. This is very handy when setting up an instrument model, which requires regular compilations.

To save the chosen settings for your next McXtrace run, use Save Configuration in the File menu.

File/Save configuration saves user settings from Configuration options and Run dialogue to disk.

File/Quit exits the graphical user interface front-end.

The **Simulation** menu has the following features:

Simulation/Read old simulation prompts for the name of a file from a previous run of a McXtrace simulation (usually called `mccode.sim`). The file will be read and any detector data plotted using the `mxplot` front-end. The parameters used in the simulation will also be made the defaults for the next simulation run. This function is also available using the “Read” button to the right of the name of the current simulation data.

Simulation/Run simulation opens the run dialog window, explained further below.

Simulation/Plot results plots (using `mxplot`) the results of the last simulation run or spawns a load dialogue to load a set of results.

Figure 5.2.: The “configuration options” dialog in `mxgui`.

The **New from Template** menu (known as “X-ray site” in older McXtrace releases) contains a list of template and example instruments as found in the McXtrace library, sorted by category/facility – see chapter ?? for a curated tour. When selecting one of these, a local copy of the instrument description is transferred to the active directory (so that users have modification rights) and loaded. One may then view its source (Edit) and use it directly for simulations/trace (3D View).

The **Tools** menu gathers minor tools.

Tools/Plot current/other results Plot current simulation results and other results.

Tools/Dataset convert/merge Opens a GUI to merge scattered data sets (e.g. from successive runs or an MPI job) or assemble scan sets.

Tools/Shortcut keys displays the shortcut keys used for running and editing instruments.

The **Help** menu has the following features, through use of `mxdoc` and a web browser. To customize the used web browser, set the `BROWSER` environment variable. If `BROWSER` is not set, `mxgui` uses `netscape/mozilla/firefox` on Unix/Linux and the default browser on Windows.

Help/McXtrace User manual calls `mxdoc --manual`, brings up the local pdf version of this manual, using a web browser.

Help/McXtrace Component manual calls `mxdoc --comps`, brings up the local pdf version of the component manual, using a web browser.

Help/Component library index displays the component documentation using the component `index.html` index file.

Help/McXtrace web page calls `mxdoc --web`, brings up the McXtrace website in a web browser.

Help/Current instrument info generates a description web-page of the current edited instrument.

Help/Test McXtrace installation launches `mxtest` to check that the McXtrace package is installed properly and generates accurate results.

Help/Generate component index (re-)generates locally the component `index.html`.

The run dialog

Figure 5.3.: The run dialog in `mxgui`.

The run dialog is used to run simulations. It allows the entry of instrument parameters as well as the specifications of options for running the simulation (see section 5.4 for details). It also allows to run the `mxdisplay` (section 5.5.4) and `mxplot` (section 5.5.5) front-ends together with the simulation.

The meaning of the different fields is as follows:

Run:Instrument parameters allows the setting of the values for the input parameters of the instrument. The type of each instrument parameter is given in parenthesis after each name. Floating point numbers are denoted by (D) (for the C type “double”), (I) denotes integer parameters, and (S) denotes strings. For parameter scans and optimizations, enter the minimum and maximum values to scan/optimize, separated by a comma, e.g. `1,10` and do not forget to set the **# Scanpoints** to more than 1.

Run:Output to allows the entry of a directory for storage of the resulting data files (like the `--dir` option). If no name is given, the results are stored in the current directory, to be overwritten by the next simulation.

Run:Force Forces McXtrace to overwrite existing data files

X-ray count sets the number of x-rays to simulate (the `--ncount` option).

Run:Random seed/Set seed to selects between using a random seed (different in each simulation) for the random number generator, or using a fixed seed (to reproduce results for debugging).

Run:Simulate/Trace (3D)/Optimize selects between several modes of running the simulation:

- Simulate: perform a normal simulation or a scan when `#steps` is set to non-zero value
- Trace (3D view): View the instrument in 3D tracing individual x-rays through the instrument
- Optimize: find the optimum value of the simulation parameters in the given ranges (see section 5.4.5).
- Backgrounding (bg): Simulate or Optimize in the background.

Run:# steps / # optim sets the number of simulation to run when performing a parameter scan or the number of iterations to perform in optimization mode.

Run:Plot results – if checked, the `mxplot` front-end will be run after the simulation has finished, and the plot dialog will appear (see below).

Run:Format quick selection of output format (`McXtrace` or `NeXus`).

Run:Clustering method selects between running locally or via MPI. See section 5.7 on parallel computing for more informations.

Run:Number of nodes sets the number of MPI nodes to use.

Run:Inspect component (Trace mode) will trace only x-ray trajectories that reach a given component (e.g. sample or detector).

Run:First component (Trace mode) selects the first component to plot (default is first) in order to define a region of interest.

Run:Last component (Trace mode) selects the last component to plot (default is first) in order to define a region of interest.

Run:Maximize monitor (Optimization mode) selects up to three monitors which integral value should be maximized, varying instrument parameters. If no monitor is selected, the sum of all monitors is optimized.

Run:Start runs the simulation.

Run:Cancel aborts the dialog.

Most of the settings on the run dialog can be saved for your next `McXtrace` run using 'Save configuration' in the File menu.

Before running the simulation, the instrument definition is automatically compiled if it is newer than the generated C file (or if the C file is newer than the executable). The executable is assumed to have a `.out` suffix in the filename. NB: If components are changed, automatic compilation is *not* performed. Instead, use the File/Compile menu item in `mxgui`.

The editor window

The editor window provides a simple editor for creating and modifying instrument definitions. Apart from the usual editor functions, the “Insert” menu provides some functions that aid in the construction of the instrument definitions:

Editor Insert/Instrument template inserts the text for a simple instrument skeleton in the editor window.

Editor Insert/Component... opens up a dialog window with a list of all the components available for use in McXtrace. Selecting a component will display a description. Double-clicking will open up a dialog window allowing the entry of the values of all the parameters for the component (figure 5.4). See section 6.3 for details of the meaning of the different fields.

The dialog will also pick up those of the users own components that are present in the current directory when `mxgui` is started. See section 6.7 for how to write components to integrate well with this facility.

Editor Insert/Type These menu entries give quick access to the entry dialog for the various component types available, i.e. Sources, Optics, Samples, Monitors, Misc, Contrib and Obsolete.

5.5.2. Running simulations on the commandline (`mxrun`)

The `mxrun` front-end provides a convenient command-line interface for running simulations with the same automatic compilation features available in the `mxgui` front-end. It also provides a facility for running a series of simulations while varying an input parameter.

The command

```
1 mxrun sim args ...
```

will compile the instrument definition `sim.instr` (if necessary) into an executable simulation `sim.out`. It will then run `sim.out`, passing the argument list `args`

The possible arguments are the same as those accepted by the simulations themselves as described in section 5.4, with the following extensions:

- The `-c` or `--force-compile` option may be used to force the recompilation of the instrument definition, regardless of file dates. This may be needed in case any component definitions are changed (in which case `mxrun` does not automatically recompile), or if a new version of McXtrace has been installed.

Figure 5.4.: Component parameter entry dialog.

- The `-p file` or `--param=file` option may be used to specify a file containing assignment of values to the input parameters of the instrument definition. The file should consist of specifications of the form *name=value* separated by spaces or line breaks. Multiple `-p` options may be given together with direct parameter specifications on the command line. If a parameter is assigned multiple times, later assignments override previous ones.
- The `-N count` or `--numpoints=count` option may be used to perform a series of *count* simulations while varying one or more parameters within specified intervals. Such a series of simulations is called a *scan*. To specify an interval for a parameter *X*, it should be assigned two values separated by a comma. For example, the command

```
1 mxrun sim.instr -N4 X=2,8 Y=1
```

would run the simulation defined in `sim.instr` four times, with *X* having the values 2, 4, 6, and 8, respectively.

After running the simulation, the results will be written to the file `mccode.dat` by default (see the `--optimise-file` option). This file contains one line for each simulation run giving the values of the scanned input variables along with the integrated intensity and estimated error in all monitors. This file can be plotted with any of the `mxplot` backends, see section 5.5.5.

- When performing a scan, the `-f file` and `--file=file` options make `mxrun` write the output to the files `file.dat` and `file.sim` instead of the default names.

- When performing a scan, the `-d dir` and `--dir=dir` options make `mxrun` put all output in a newly created directory *dir*. Additionally, the directory will have subdirectories 1, 2, 3, ... containing all data files output from the different simulations. When the `-d` option is not used, no data files are written from the individual simulations (in order to save disk space).

The `-h` option will list valid options; see also Table 5.1 for the complete, current option list.

5.5.3. GPU acceleration via OpenACC

McXtrace 3.x supports GPU-accelerated simulations through the OpenACC framework, enabling substantial speed-ups over CPU-only execution on compatible NVIDIA hardware.

Requirements

- **Compiler:** NVIDIA HPC SDK version 20.x or newer. The free Community Edition is sufficient.
- **Hardware:** A CUDA-capable NVIDIA GPU with an up-to-date driver.
- **Platform:** GPU support is currently available on Linux only. Windows is not yet supported for OpenACC by NVIDIA; Windows users wishing to use GPU acceleration should do so via WSL 2 running a Linux distribution.

Running a GPU-accelerated simulation

Pass the `--openacc` flag to `mxrun`:

```
mxrun --openacc MyInstrument.instr -n 1e9
```

Combined multi-core + GPU execution. It is also possible to use both CPU cores and the GPU simultaneously. Enable this by adding the following to the `OACCFLAGS` field of your `mccode_config.json`:

```
"OACCFLAGS": "-fast -Minfo=accel -acc=gpu,multicore  
-gpu=managed -DOPENACC -DMULTICORE"
```

Further information

GPU terminology specific to McStas/McXtrace 3 and detailed debugging tips are documented on the McCode wiki:

- GPU terminology table:
<https://github.com/mccode-dev/McCode/wiki/McStas-McXtrace-3-and-GPU-terminology>
- GPU debugging tips:
<https://github.com/mccode-dev/McCode/wiki/GPU-Debugging-tips>

5.5.4. Graphical display of simulations (mxdisplay)

The front-end `mxdisplay` is a graphical visualization tool, very useful for debugging. It presents a schematic drawing of the instrument definition, showing the position of the components and the paths of the simulated x-rays through the instrument. It is thus very useful for debugging a simulation, for example to spot components in the wrong position or to find out where x-rays are getting lost.

To use the `mxdisplay` front-end with a simulation, run it as follows:

```
1 mxdisplay sim args ...
```

where `sim` is the name of either the instrument source `sim.instr` or the simulation program `sim.out` generated by `mcxtrace`, and `args ...` are the normal command line arguments for the simulation, as explained above. The `-h` option will list valid options.

The drawing back-end may be selected by invoking one of the dedicated front-ends directly:

- `mxdisplay-pyqtgraph` (the default when running plain `mxdisplay`): interactive PyQtGraph 3D view.
- `mxdisplay-matplotlib`: static/interactive matplotlib 3D view.
- `mxdisplay-webgl` and `mxdisplay-webgl-classic`: browser-based WebGL views (the former uses a small NodeJS-backed server for larger instruments/particle counts).
- `mxdisplay-cad`: exports the instrument geometry to a CAD-compatible format.

For instance, calling

```
1 mxdisplay-webgl ./MAXII.711.out R=90
```

will open a WebGL view of the instrument in a browser tab. The `mxdisplay` front-end can also be run from the `mxgui` front-end.

The (default, PyQtGraph) front-end accepts the following options, amongst others – run `mxdisplay --help` for the complete, current list:

- `--default`: automatically use the instrument's default parameter values, without prompting.
- `--dirname=DIR`: override the output directory name used while tracing.
- `--inspect=comp`: only display x-ray trajectories that reach the component named `comp`. This is useful when debugging, e.g. to hide x-rays absorbed upstream of the component of interest.
- `--invcanvas`: invert the canvas background from black to white (useful for printing or screenshots).
- `-n/--ncount=N`: number of x-rays to trace.

When debugging trajectories through a long or complex instrument, combining `--inspect` with a modest `--ncount` typically gives the clearest, fastest picture of what is happening around a particular component.

5.5.5. Plotting the results of a simulation (mxplot)

The front-end `mxplot` is a program that produces plots of all the monitors in a simulation, and it is thus useful to get a quick overview of the simulation results.

In the simplest case, the front-end is run simply by typing

```
1 mxplot
```

This will plot any simulation data stored in the current directory, which is where simulations store their results by default. If the `--dir` or `--file` options have been used (see section 5.4), the name of the file or directory should be passed to `mxplot`, *e.g.* “`mxplot dir`” or “`mxplot file`”. It is also possible to plot one single text (not binary) data file from a given monitor, passing its name to `mxplot`.

As with `mxdisplay` (section 5.5.4), the drawing back-end may be selected by invoking the dedicated front-end directly: `mxplot-pyqtgraph` (the default), `mxplot-matplotlib`, or `mxplot-html` (renders an interactive, self-contained web page using D3.js, see section 5.4.2), or by setting the `MCXTRACE_FORMAT` environment variable.

All plotters read the plain-text McXtrace/McCode data format (section 5.6); NeXus files are not currently read back by the plotters.

The `mxplot` front-end can also be run from the `mxgui` front-end.

The initial display shows plots for each detector in the simulation.

Comparing two simulation results: `mxplotdiff-html` and `mxcoplot-html`. Two companion browser-based tools reuse `mxplot-html`’s plotting code to compare a pair of simulation results (two output directories, or two single monitor files), matching monitors by output filename:

- `mxplotdiff-html a b` plots, for every monitor present with matching binning in both `a` and `b`, the difference `a - b` (with error-propagated error bars for 1D monitors, and a diverging blue/white/red colour scale for 2D monitors). This is useful to quickly spot the effect of a component or parameter change, an McXtrace version upgrade, or MPI vs. non-MPI results. By default, each difference is also written back out as a normal McXtrace/McCode-format data set (with an `mccode.sim` index), so the result directory can be reopened by any other McCode-format-aware plotter; pass `--no-dat` to skip this.
- `mxcoplot-html a b` instead overlays the two datasets’ 1D monitors on the same axes (only 1D monitors are supported), for a direct visual comparison of curve shape and position.

Both accept `-A LABEL_A/-B LABEL_B` to control the labels used for each input, and `-o OUTPUT` to control the output directory name; run either with `--help` for the complete

option list. `mxplotdiff-html` is also used internally by `mxviewtest` to compare test runs against a reference.

5.5.6. Creating and viewing the library, component/instrument help and Manuals (`mxdoc`)

McXtrace provides an easy way to generate automatically an HTML help page about a given component or instrument, or the whole McXtrace library.

```
1 mxdoc
2 mxdoc searchterm
3 mxdoc file.comp
```

The first example generates an `index.html` catalog file using the available components and instruments (both locally, and in the McXtrace library), and browses it using the `BROWSER` environment variable (e.g. `firefox`, `chromium`, ...). Alternatively, if a search term or a `file.comp/file.instr` path is given, `mxdoc` will search within the library and open documentation for all matching entries.

Additional options include `--install/-i` (regenerate the local installation-wide index), `--dir=DIR/-d` (add search results from a given directory), and `--verbose/-v` (print a parsing log). The options `--manual/-m`, `--comps/-c` and `--web/-w` will open the User Manual (this document), the Component Manual, and the McXtrace web site, respectively, all requiring `BROWSER` to be defined. Finally, the `--help` option will display the command help, as usual.

See section 6.7 for more details about the McDoc usage and header format. `mxdoc` is a pure Python tool, part of the standard McXtrace conda-forge package.

5.5.7. Self-testing the installation (`mxtest`, `mxviewtest`)

McXtrace ships with a Python self-test/benchmark harness. `mxtest` compiles and runs a selection (or all) of the example instruments found under the current installation(s), and stores each run's results (including any test-defined `%Example` reference values) in a timestamped output folder. Useful options include `--ncount`, `--mpi` and `--openacc` (forwarded to `mxrun` for every tested instrument), `--config=LABEL` (test only a specific McCode installation/config), `--instr=REGEX` (test only matching instrument names), and `--limit=N` (test only the first N instruments per version); run `mxtest --help` for the full list.

`mxviewtest` then generates an HTML report of one or more `mxtest` runs found in a given folder (the current directory by default). When more than one run is present (e.g. a reference run and a run on a different platform, GPU vs. CPU, or a different McXtrace branch), it takes the oldest subfolder as the reference column, and additionally runs `mxplotdiff-html` (section 5.5.5) between each other column's monitor output and the reference's, adding a `DIFF [vs ref]` link next to each such row in the report. These comparisons are cached on disk and generated in parallel (`--diffworkers`), so re-running `mxviewtest` is fast; use `--nodiff` to skip generating them entirely, or `--diff-errors-only` to only diff rows that already show a discrepancy.

5.6. Data formats - Analyzing and visualizing the simulation results

To analyze simulation results, one uses the same tools as for analyzing experimental data, *i.e.* programs such as Python/NumPy, Matlab, IDL. The output files from simulations are usually simple text files containing headers and data blocks. If data blocks are empty they may be accessed referring to an external file indicated in the header.

Each data file contains information about the simulation, the instrument, the parameters used, and of course the signal, the estimated error on the signal, and the number of events used in each bin. Additionally, all data files indicate their first moment (mean value) and second moment (half width) in the 'statistics' field.

The available data formats are the legacy McXtrace (McCode) format, and the HDF/NeXus binary when the needed libraries are installed.

In order for the user to choose the data format, we recommend to set it using the `--format=FORMAT` or alternatively *via* the `MCXTRACE_FORMAT` environment variable, which will also make the front-end programs able to import and plot data and instrument consistently (see Section 5.4).

Note that the x-ray event counts in detectors are typically not very meaningful except as a way to measure the performance of the simulation. Use the simulated intensity instead whenever analyzing simulation data.

5.6.1. The McXtrace/McCode text format

The McXtrace original format, simply columns of ASCII text that most programs should be able to read.

One-dimensional histogram monitors (energy, wavelength) write one line for each histogram bin. Each line contains a number identifying the bin followed by three numbers: the simulated intensity, an estimate of the statistical error as explained in section 4.2.1, and the number of x-ray events for this bin.

Two-dimensional histogram monitors (position sensitive detectors) output M lines of N numbers representing x-ray intensities, where M and N are the number of bins in the two dimensions. The two-dimensional monitors also store the error estimates and event counts as additional matrices.

Single-point monitors output the x-ray intensity, the estimated error, and the x-ray event count as numbers on the terminal. (The results from a series of simulations may be combined in a data file using the `mxrun` front-end as explained in section 5.5.2).

When using one- and two-dimensional monitors, the integrated intensities are written to terminal as for the single-point monitor type, supplementing file output of the full one- or two-dimensional intensity distribution. Both one- and two-dimensional monitor output by default start with a header of comment lines, all beginning with the '#' character. This header gives such information as the name of the instrument used in the simulation, the values of any instrument parameters, the name of the monitor component for this data file, *etc.* The headers may be disabled using the `--data-only` option in case the file must be read by a program that cannot handle the headers.

In addition to the files written for each one- and two-dimensional monitor component, another file (by default named `mccode.sim`) is also created. This file is in a special McXtrace ASCII format. It contains all available information about the instrument definition used for the simulation, the parameters and options used to run the simulation, and the monitor components present in the instrument. It is read by the `mxplot` front-end (see section 5.5.5). This file stores the results from single monitors, but by default contains only pointers (in the form of file names) to data for one- and two-dimensional monitors. By storing data in separate files, reading the data with programs that do not know the special McXtrace file format is simplified. The `--file` option may be used to store all data inside the `mccode.sim` file instead of in separate files.

5.6.2. NeXus format

The NeXus format [Nex] is a platform independent HDF binary data file. To have McXtrace use it

1. the HDF and NeXus libraries must have been installed (libNeXus and headers)
2. the compilation of instruments must be done with the `-DUSE_NEXUS -lNeXus` flag (see Section 6.3.4). This is automated with the `mxrun` tool (Section 5.5.2).

All results are saved in a single file, containing 'groups' of data. To view such files, install and use HDFView (or alternatively HDFExplorer). This Java viewer can show content of all detectors, including metadata (attributes). Basic detector images may also be generated.

5.7. Using MPI for parallel computing

Parallelizing a computation is in general possible when dependencies between each computation are not too strong. The situation of McXtrace is ideal since each x-ray can be simulated without interfering with other simulated x-rays. Therefore each x-ray can be simulated independently on a set of computers.

When computing N x-rays with p computers, each computer will simulate $\frac{N}{p}$ x-rays. As a result there will be $p \cdot \frac{N}{p} = N$ x-rays simulated. As a result, McXtrace generates two kinds of data sets:

- intensity measurements, internally represented by three values (p_0, p_1, p_2) where p_0, p_1, p_2 are additive. Therefore the final value of p_0 is the sum of all local value of p_0 computed on each node. The same rule applies for p_1 and p_2 . The evaluation of the intensity errors σ is performed using the final p_0, p_1 , and p_2 arrays (see Section 4.2.1).
- event lists: the merge of events is done by concatenation

McXtrace provides two methods in order to distribute computations on many computers.

- when using an homogeneous computer cluster, each simulation (including scan steps) may be computed in parallel using MPI. We recommend this method on clusters (see section 5.7.1).
- `mxrun`'s built-in scan-splitting (`--scan_split=N`, see Table 5.1) distributes the individual steps of a parameter scan across `N` local CPU cores/threads, without requiring MPI. This is a lightweight alternative on a single multi-core machine.

All of these methods can be used, when available, from `mxgui`.

5.7.1. Parallel computing (MPI)

The MPI support requires that an MPI implementation (MPICH or OpenMPI are both known to work) is installed on a set of nodes, together with a properly configured passwordless `ssh` between nodes if running across more than one machine.

There are 2 methods for using MPI

- Basic usage requires to compile and run the simulation by hand (`mpicc`, `mpirun`).
- A much simpler way is to use `mxrun -c --mpi=NB_CPU ...` which will recompile and run with MPI support.
- The `mxgui` interface also supports MPI from within the Run Dialog.

The MPI support is especially suited on clusters.

Requirements and limitation (MPI)

To use MPI you will need

1. A working MPI installation (MPICH or OpenMPI) on all nodes, and a McXtrace installation accessible from all nodes (e.g. on a shared filesystem, or installed identically on each node).
2. If running across more than one machine, `ssh` access between nodes without a password (e.g. using `ssh-keygen` and `ssh-copy-id`), and a machine list file (see `--machines` in Table 5.1).
3. Signals are *not* supported while simulating with MPI (since asynchronous events cannot be easily transmitted to all nodes). This means it is not possible to cancel an on-going computation. However, simulation scans can be interrupted as soon as the on-going computation step ends.

MPI Basic usage

To enable parallel computation, compile `mcxtrace`-generated C code with `mpicc` with the flag `-DUSE_MPI` and run it using the wrapper of your MPI implementation (`mpirun` for `mpich` or `lambmpi`) :

```

1  # generate a C-source file [sim.c]
2  mcxtrace sim.instr
3
4  # generate an executable with MPI support [sim.mpi]
5  mpicc -DUSE_MPI -o sim.mpi sim.c
6
7  # execute with parallel processing over <N> computers
8  # here you have to list the computers you want to use
9  # in a file [machines.list] (using mpich implementation)
10 # (refer to MPI documentation for a complete description)
11 mpirun -machinefile machines.list -n <N> \
12     ./sim.mpi <instrument parameters>
13 ...

```

If you don't want to spread the simulation, run it as usual:

```

1  ./sim.mpi <instrument parameters>

```

5.7.2. McRun options for MPI

The two relevant `mxrun` options are (see Table 5.1):

- `--mpi=<number>`: tells `mxrun` to use MPI, and to spread the simulation over `<number>` nodes
- `--machines=<file>`: defines a text file where the nodes which are to be used for parallel computation are listed, one node per line.

When available, the MPI option will show up in the `mxgui` Run dialog. Specify the number of nodes required.

Suppose you have four machines named `node1` to `node4`. A typical machine list file, `machines.list` looks like :

```

1 node1
2 node2
3 node3
4 node4

```

You can then spread a simulation `sim.instr` using `mxrun` :

```

1  mxrun -c --mpi=4 --machines=machines.list \
2  sim.instr <instrument parameters>

```

Warning: when using `mxrun` with MPI, be sure to recompile your simulation with MPI support (see `-c` flag of `mxrun`): a simulation compiled without MPI support cannot be used with MPI, whereas a simulation compiled with MPI support can be used without MPI.

5.7.3. McXtrace/MPI Performance

Theoretically, a computation which lasts T seconds on a single computer, should last at least $\frac{T}{p}$ seconds when it is distributed over p computers. In practice, there will be overhead time due to the split and merge operations.

- the split is immediate: constant time cost $\mathcal{O}(1)$
- the merge is at worst linear against the number of computers:
 - linear time cost : $\mathcal{O}(p)$ when saving an event list
 - logarithmic time cost: $\mathcal{O}(\log p)$ when not saving an event list

The efficiency of McXtrace using MPI has been tested on large clusters. The computation time decreases in the same proportion as the number of nodes, showing an ideal efficiency. However, a small overhead may appear depending on the cluster internal network load, which may be estimated at most of about 10-20 s. This overhead comes from the spread and the fusion of the computations. For instance, spreading a computation implies often an `rsh` or `ssh` session to be opened on every node. To reach the best efficiency, the computation time should not be lower than 30 seconds, or the overhead time may become significant compared to total time.

5.7.4. MPI Bugs and limitations

- Some header of output files might contain minor errors.
- The computation split does not take into account the speed or the load of nodes: the overall time of a distributed computation is forced by the slowest node; for optimal performance, the “cluster” should be homogeneous.
- Interacting with a running simulation (USR1 and USR2 signals) is disabled with MPI.

6. The McXtrace kernel and meta-language

Beamline definitions are written in a special McXtrace meta-language which is translated automatically by the McXtrace compiler into a C program which is in turn compiled to an executable that performs the simulation. The meta-language is custom-designed for x-ray scattering and serves two main purposes: (i) to specify the interaction of a single x-ray with a single optical component, and (ii) to build a simulation by constructing a complete beamline from individual components.

For maximum flexibility, efficiency and portability, the meta-language is based on C. Instrument geometry, propagation of x-rays between the different components, parameters, data input/output etc. is handled in the meta-language and by the McXtrace compiler. Complex calculations are written in C embedded in the meta-language description of the components. However, it is possible to set up an instrument from existing components and run a simulation without writing a single line of C code, working entirely in the meta-language.

Apart from the meta-language, McXtrace also includes a number of C library functions and definitions that are useful for x-ray tracing simulations. The definitions available for component developers are listed in appendix B. The list includes functions for

- Computing the intersection between a photon flight-path and various objects (such as planes, cylinders, boxes and spheres).
- Functions for generating random numbers with various distributions.
- Functions for reading or writing informations from/to data files.
- Convenient conversion factors between relevant units, etc.

The McXtrace meta-language was designed to be readable, with a verbose syntax and explicit mentioning of otherwise implicit information. The recommended way to get started with the meta-language is to start by looking at the examples supplied with McXtrace, modifying them as necessary for the application at hand.

6.1. Notational conventions

Simulations generated by McXtrace use a semi-classical description of the x-rays to compute the x-ray trajectory through the instrument and its interaction with the different components.

An instrument consists of a list of components through which the x-ray ray passes one after the other. The order of components is thus significant since McXtrace does not

Figure 6.1.: conventions for the orientations of the axis in simulations.

automatically check which component is the next to interact with the x-ray at a given point in the simulation. Note that in case of a negative propagation length from one component to the next, the x-ray is by default *absorbed* as this is often an indication of unphysical conditions. If a large part of the simulated rays are *absorbed* on account of this a warning is issued, as this is often caused by a misplaced component.

The instrument is given a global, absolute coordinate system. In addition, every component in the instrument has its own local coordinate system that can be given any desired position and orientation (though the position and orientation must remain fixed for the duration of a single simulation). By convention, the z axis points in the direction of the beam, the x axis is perpendicular to the beam in the horizontal plane pointing left as seen from the source, and the y axis points upwards (see fig. 6.1). Nothing in the McXtrace metalanguage enforces this convention, but if every component used different conventions the user would be faced with a severe headache! It is therefore necessary that this convention is followed by users implementing new components.

In the instrument definitions, units of length (*e.g.* component positions) are given in meters and units of angles (*e.g.* rotations) are given in degrees. The state of the x-ray is given by its position (x, y, z) in m, its wavevector (k_x, k_y, k_z) in $\text{\AA}^{-1}$, the time in s, the phase ϕ in rad, and a polarisation vector (E_x, E_y, E_z) , and finally the x-ray weight p in photons s as described in chapter 4.

6.2. Syntactical conventions

Comments follow the normal C syntax “`/* ... */`”. C++ style comments “`// ...`” may also be used.

Keywords are not case-sensitive, for example “`DEFINE`”, “`define`”, and “`dEfInE`” are all equivalent. However, by convention we always write keywords in uppercase to distinguish them from identifiers and C language keywords. In contrast, McXtrace identifiers (names), like C identifiers and keywords, *are* case sensitive, another good reason to use a consistent case convention for keywords. All McXtrace keywords are reserved, and thus

should not be used as C variable names. The list of these reserved keywords is shown in table 6.1.

It is possible, and usual, to split the input instrument definition across several different files. For example, if a component is not explicitly defined in the instrument, McXtrace will search for a file containing the component definition in the standard component library (as well as in the current directory and any user-specified search directories, see section 5.3.2). It is also possible to explicitly include another file using a line of the form

```
%include "file"
```

Beware of possible confusion with the C language “`#include`” statement, especially when it is used in C code embedded within the McXtrace meta-language. Files referenced with “`%include`” are read when the instrument is translated into C by the McXtrace compiler, and must contain valid McXtrace meta-language input (and possibly C code). Files referenced with “`#include`” are read when the C compiler generates an executable from the generated C code, and must contain valid C.

Embedded C code is used in several instances in the McXtrace meta-language. Such code is copied by the McXtrace compiler into the generated simulation C program. Embedded C code is written by putting it between the special symbols `%{` and `%}`, as follows:

```
%{  
... Embedded C code ...  
%}
```

The “`%{`” and “`%}`” must appear on a line by themselves (do not add comments after). Additionally, if a “`%include`” statement is found *within* an embedded C code block, the specified file will be included from the ‘share’ directory of the standard component library (or from the current directory and any user-specified search directories) as a C library, just like the usual “`#include`” *but only once*. For instance, if many components require to read data from a file, they may all ask for “`%include "read_table-lib"`” without duplicating the code of this library. If the file has no extension, both `.h` and `.c` files will be searched and included, otherwise, only the specified file will be imported. The McXtrace ‘run-time’ shared library is included by default (equivalent to “`%include "mcxtrace-r"`” in the `DECLARE` section). For an example of `%include`, see the `optics/Lens_simple.comp` component. See also section 6.4.2 for insertion of full instruments in instruments (instrument catenation).

If the instrument description compilation fails, check that the keywords syntax is correct, that no semi-colon `;` sign is missing (e.g. in C blocks and after an `ABSORB` macro), and there are no name conflicts between instrument and component instances variables.

Keyword	Scope	Meaning
ABSOLUTE	I	Indicates that the AT and ROTATED keywords are in the absolute coordinate system.
AT	I	Indicates the position of a component in an instrument definition.
COPY	I,C	copy/duplicate an instance or a component definition.
DECLARE	I,C	Declares C internal variables.
DEFINE	I,C	Starts an INSTRUMENT or COMPONENT definition.
DEFINITION	C	Defines component parameters that are constants (#define).
END	I,C	Ends the instrument or component definition.
SPLIT	I	Enhance incoming statistics by event repetition.
EXTEND	I	Extends a component TRACE section (plug-in).
FINALLY	I,C	Embeds C code to execute when simulation ends.
GROUP	I	Defines an exclusive group of components.
%include	I,C	Imports an instrument part, a component or a piece of C code (when within embedded C).
JUMP	I	Iterative (loops) and conditional jumps.
INITIALIZE	I,C	Embeds C code to be executed when starting.
ITERATE	I	Defines iteration counter for JUMP.
MCDISPLAY	C	Embeds C code to display component geometry.
NEXUS	I	Defines NeXus output type (4,5,XML,compression).
OUTPUT	C	Defines internal variables to be public and protected symbols (usually all global variables and functions of DECLARE).
PARAMETERS	C	Defines a class of component parameter (DEFINITION, SETTING, STATE).
PREVIOUS	C	Refers to a previous component position/orientation.
RELATIVE	I	Indicates that the AT and ROTATED keywords are relative to an other component.
ROTATED	I	Indicates the orientation of a component in an instrument definition.
SAVE	I,C	Embedded C code to execute when saving data.
SETTING	C	Defines component parameters that are variables.
SHARE	C	Declares global functions and variables to be shared.
STATE	C	Defines x-ray state coordinates.
TRACE	I,C	Defines the instrument as a the component sequence.
WHEN	I	Condition for component activation and JUMP.

Table 6.1.: Reserved McXtrace keywords. Scope is 'I' for instrument and 'C' for component definitions.

6.3. Writing instrument definitions

The purpose of the instrument definition file is to specify a sequence of components, along with their position and parameters, which together make up a beamline. Each component is given its own local coordinate system, the position and orientation of which may be specified by its translation and rotation relative to another component. Examples of instrument definitions can be found in the `example` directory of your McXtrace installation. Further examples may be found as they are built on the McXtrace web-page [Mcx].

As a summary, the usual grammar for instrument descriptions is

```
DEFINE INSTRUMENT name(parameters)
DECLARE C_code
INITIALIZE C_code {NEXUS}
TRACE components
{FINALLY C_code}
END
```

6.3.1. The instrument definition head

```
DEFINE INSTRUMENT name ( $a_1, a_2, \dots$ )
```

This marks the beginning of the definition. It also gives the name of the instrument and the list of instrument parameters. Instrument parameters describe the configuration of the instrument, and usually correspond to setting parameters of the components, see section 6.5. A motor position is a typical example of an instrument parameter. The input parameters of the instrument constitute the input that the user (or possibly a front-end program) must supply when the generated simulation is started.

By default, the parameters will be floating point numbers, and will have the C type `double` (double precision floating point). The type of each parameter may optionally be declared to be `int` for the C integer type or `char *` for the C string type. The name `string` may be used as a synonym for `char *`, and floating point parameters may be explicitly declared using the name `double`. The following example illustrates all possibilities:

```
DEFINE INSTRUMENT test(d1, double d2, int i, char *s1, string s2)
```

Here `d1` and `d2` will be floating point parameters of C type `double`, `i` will be an integer parameter of C type `int`, and `s1` and `s2` will be string parameters of C type `char *`. The parameters of an instrument may be given default values. Parameters with default values are called *optional parameters*, and need not be given an explicit value when the instrument simulation is executed. When executed without any parameter value in the command line (see section 5.4), the instrument asks for all parameter values, but pressing the **Return** key selects the default value (if any). When used with at least one parameter value in the command line, all non specified parameters will have their value

set to the default one (if any). A parameter is given a default value using the syntax “*param= value*”. For example

```
DEFINE INSTRUMENT test(d1= 1, string s2="hello")
```

Here *d1* and *d2* are optional parameters and if no value are given explicitly, “1” and “hello” will be used.

Optional parameters can greatly increase the convenience for users of instruments for which some parameters are seldom changed or of unclear significance to the user. Also, if all instrument parameters have default values, then the simple command `mxdisplay test.instr` will show the instrument view without requesting any other input, which is usually a good starting point to study the instrument design.

6.3.2. The DECLARE section

```
DECLARE
%{
    ... C declarations of global variables etc. ...
%}
```

This gives C declarations that may be referred to in the rest of the instrument definition. A typical use is to declare global variables or small functions that are used elsewhere in the instrument. The `%include 'file'` keyword may be used to import a specific component definition or a part of an instrument. Variables defined here are global, and may conflict with internal McXtrace variables, particularly symbols like *x,y,z,Ex,Ey,Ez,kx,ky,kz,t,phi* and generally all names starting with *mc* nad *mx* should be avoided. If you can not compile the instrument, this may be the reason. The `DECLARE` section is optional.

6.3.3. The INITIALIZE section

```
INITIALIZE
%{
    ... C initializations. ...
%}
```

This section contains code that is executed once when the simulation starts. This section is optional. Instrument setting parameters may be modified in this section (e.g. doing tests or automatic settings).

6.3.4. The NEXUS extension

To use the NeXus format [Nex] the simulation must be linked with additional libraries (HDF and NeXus) which must have been pre-installed. Preferably, McXtrace should have been installed with the `./configure --with-nexus` on Unix/Linux systems. To activate the NeXus output, the instrument must be compiled with the flags `-DUSE_NEXUS -lNeXus`.

The default NeXus format is NeXus 5 with compression. However, that format may be changed with the optional keyword `NEXUS` to follow the `INITIALIZE` section, namely:

```
INITIALIZE
%{
    ... C initializations. ...
}% NEXUS {"4"|"5"|"XML"|"compress"|"zip"}
```

It is possible to set the type of NeXus file with a string argument, containing words "4", "5" or "XML". Optionally, if the string also contains the `compress` or `zip` word, the NeXus file will use compression for Data Sets. We recommend the syntax `NEXUS "5 compress"` which is the default.

You may choose the name of the output file with the `-f filename` option from the instrument executable or `mxrun` (see Sections 5.4, 5.5.2 and Table ??).

Then, the output format is chosen as usual with the `--format=NeXus` option when launching the simulation. All output files are stored in the output *filename*, as well as the instrument description itself. Other formats are still available. When run on a distributed system (e.g. MPI), detectors are gathered, but list of events (see e.g. component `Virtual-output`) are stored as one data set per node.

6.3.5. The TRACE section

As a summary, the usual grammar for component instances within the instrument `TRACE` section is

```
COMPONENT name = comp(parameters)
  AT (...) [RELATIVE [reference|PREVIOUS] | ABSOLUTE]
  {ROTATED {RELATIVE [reference|PREVIOUS] | ABSOLUTE} }
```

The `TRACE` keyword starts a section giving the list of components that constitute the instrument. Components are declared like this:

```
COMPONENT name = comp( $p_1 = e_1, p_2 = e_2, \dots$ )
```

This declares a component named *name* that is an instance of the component definition named *comp*. The parameter list gives the setting and definition parameters for the component. The expressions $e_1, e_2, \dots$ define the values of the parameters. For setting parameters arbitrary ANSI-C expressions may be used, while for definition parameters only *constant* numbers, strings, names of instrument parameters, or names of C identifiers are allowed (see section 6.5.1 for details of the difference between definition and setting parameters). To assign the value of a general expression to a definition parameter, it is necessary to declare a variable in the `DECLARE` section, assign the value to the variable in the `INITIALIZE` section, and use the variable as the value for the parameter.

The McXtrace program takes care to rename parameters appropriately in the output so that no conflicts occur between different component definitions or between component and instrument definitions. It is thus possible (and common) to use a component definition multiple times in an instrument description.

Be aware of the C variable type conversions when setting numerical parameter values, as in `p1=12/1000`. In this example, the parameter `p1` will be set to 0 as the division of the two integers is indeed 0. To avoid that, use explicitly floating type numbers as in `p1=12.0/1000`.

The McXtrace compiler will automatically search for a file containing a definition of the component if it has not been declared previously. The definition is searched for in a file called “*name.comp*”. See section 5.3.2 for details on which directories are searched. This facility is often used to refer to existing component definitions in standard component libraries. It is also possible to write component definitions in the main file before the instrument definitions, or to explicitly read definitions from other files using `%include` (not within embedded C blocks).

The physical position of a component is specified using an **AT** modifier following the component declaration:

AT (*x*, *y*, *z*) **RELATIVE** *name*

This places the component at position (*x*, *y*, *z*) in the coordinate system of the previously declared component *name*. Placement may also be absolute (not relative to any component) by writing

AT (*x*, *y*, *z*) **ABSOLUTE**

Any C expression may be used for *x*, *y*, and *z*. The **AT** modifier is required. Rotation is achieved similarly by writing

ROTATED (ϕ_x, ϕ_y, ϕ_z) **RELATIVE** *name*

This will result in a coordinate system that is rotated first the angle ϕ_x (in degrees) around the *x* axis, then ϕ_y around the *y* axis, and finally ϕ_z around the *z* axis. Rotation may also be specified using **ABSOLUTE** rather than **RELATIVE**. If no rotation is specified, the default is (0,0,0) using the same relative or absolute specification used in the **AT** modifier. We recommend to apply all rotations of an instrument description on Arm class components only, acting as goniometers, and position the optics on top of these. This usually makes it much easier to orient pieces of the beamline, and avoid positioning errors.

The *position* of a component is actually the origin of its local coordinate system. Usually, this is used as the input window position (e.g. for guide-like components), or the center position for cylindrical/spherical components.

The **PREVIOUS** keyword is a generic name to refer to the previous component in the simulation. Moreover, the **PREVIOUS(n)** keyword will refer to the *n*-th previous component, starting from the current component, so that **PREVIOUS** is equivalent to **PREVIOUS(1)**. This keyword should be used after the **RELATIVE** keyword, but not for the first component instance of the instrument description.

AT (*x*, *y*, *z*) **RELATIVE** **PREVIOUS** **ROTATED** (ϕ_x, ϕ_y, ϕ_z) **RELATIVE** **PREVIOUS(2)**

Invalid **PREVIOUS** references will be assumed to be absolute placement.

The order and position of components in the **TRACE** section does not allow components to overlap, except for particular cases (see the **GROUP** keyword below). Indeed, many components of the McXtrace library start by propagating the x-ray event to the beginning of the component itself. If the corresponding propagation length is found to be negative (*i.e.* the x-ray is already *after* or *aside* the component, and has thus passed the 'active' position), the x-ray event is **ABSORBED**, resulting in a zero intensity and event counts after a given position. The number of such removed x-rays is indicated at the end of the simulation. Getting such warning messages may be an indication that either some components overlap, or some x-rays are getting outside of the simulation, for instance this usually happens after a monochromator, as the non-reflected beam is indeed lost. A special warning appears when no x-ray has reached some part of the simulation. This is usually the sign of either overlapping components or a very low intensity.

For experienced users, we recommend as well the usage of the **WHEN** and **EXTEND** keywords, as well as other syntax extensions presented in section 6.4.2 below.

6.3.6. The **SAVE** section

```
SAVE
%{
    ... C code to execute each time a temporary save is required ...
%}
```

This gives code that will be executed when the simulation is requested to save data, for instance when receiving a **USR2** signal (on Unix systems), or using the **Progress_bar** component with intermediate savings. It is also executed when the simulation ends. This section is optional.

6.3.7. The **FINALLY** section

```
FINALLY
%{
    ... C code to execute at end of simulation ...
%}
```

This gives code that will be executed when the simulation has ended. When existing, the **SAVE** section is first executed. The **FINALLY** section is optional. A simulation may be requested to end before all x-rays have been traced when receiving a **TERM** or **INT** signal (on Unix systems), or with Control-C, causing code in **FINALLY** to be evaluated.

6.3.8. The end of the instrument definition

The end of the instrument definition must be explicitly marked using the keyword

```
END
```

6.4. Writing instrument definitions - complex arrangements and syntax

In this section, we describe some additional ways to build instruments using groups, code extension, conditions, loops and duplication of components.

As a summary, the nearly complete grammar definition for component instances within the instrument TRACE section is:

```
{SPLIT} COMPONENT name = comp(parameters) {WHEN condition}  
  AT (...) [RELATIVE [reference|PREVIOUS] | ABSOLUTE]  
  {ROTATED {RELATIVE [reference|PREVIOUS] | ABSOLUTE} }  
  {GROUP group_name}  
  {EXTEND C_code}  
  {JUMP [reference|PREVIOUS|MYSELF|NEXT] [ITERATE number_of_times | WHEN condition]}
```

6.4.1. Embedding instruments in instruments TRACE

The `%include` insertion mechanism may be used within the TRACE section, in order to concatenate instruments. This way, each DECLARE, INITIALIZE, SAVE, and FINALLY C blocks, as well as instrument parameters from each part are catenated. The TRACE section is made of inserted COMPONENTS from each part. In principle, it then possible to write an instrument as:

```
DEFINE catenated()  
TRACE  
  
%include "part1.instr"  
%include "part2.instr"  
  
END
```

where each inserted instrument is a valid full instrument. In order to avoid some components to be duplicated - e.g. Sources from each part - a special syntax in the TRACE section

```
INSTRUMENT COMPONENT a=...
```

marks the component *a* as removable when inserted. In principle, inserted instruments may themselves use `%include`.

6.4.2. Component extensions - EXTEND

It is sometimes desirable to slightly modify an existing component of the McXtrace library. One would usually make a copy of the component, and extend the code of its TRACE section. McXtrace provides an easy way to change the behaviour of existing components in an instrument definition without duplicating files, using the `EXTEND` modifier

```

EXTEND
%{
    ... C code executed after the component TRACE section ...
%}

```

The embedded C code is appended to the component **TRACE** section, and all its internal variables (as well as all the **DECLARE** instrument variables, *except* instrument parameters) may be used. To use instrument parameters, you should copy them into global variables in the **DECLARE** instrument section, and refer to these latter. This component declaration modifier is of course optional. You will find usage examples in the Component manual[BK+12].

6.4.3. Mutually exclusive components in parallel - **GROUP**

In some configurations it is necessary to position one or more groups of components, nested, in parallel, or overlapping. One example is a multiple crystal monochromator. One would then like the x-ray to interact with *one of* the components of the group and then continue.

In order to handle such arrangements without removing x-rays, groups are defined by the **GROUP** modifier (after the **AT-ROTATED** positioning):

```
GROUP name
```

to all involved component declarations. All components of the same named group are tested one after the other, until one of them interacts (uses the **SCATTER** macro). The selected component acts on the x-ray, and the rest of the group is skipped. Such groups are thus exclusive (only one of the elements is active).

Within a **GROUP**, *all* **EXTEND** sections of the group are executed. In order to discriminate components that are active from those that are skipped, one may use the **SCATTERED** flag, which is set to zero when entering each component or group, and incremented when the x-ray is **SCATTERed**, as in the following example

```

COMPONENT name0 = comp( $p_1 = e_1, p_2 = e_2, \dots$ )
    AT (0,0,0) ABSOLUTE
COMPONENT name1 = comp(...) AT (...) ROTATED (...)
    GROUP GroupName EXTEND
    %{
        if (SCATTERED) printf("I scatter");
        else printf("I do not scatter");
    %}
COMPONENT name2 = comp(...) AT (...) ROTATED (...)
    GROUP GroupName

```

Components *name1* and *name2* are at the same position. If the first one intercepts the x-ray (and has a **SCATTER** within its **TRACE** section), the **SCATTERED** variable becomes true, the code extension will result in printing "I scatter", and the second component

will be skipped. Thus, we recommend to make use of the SCATTER keyword each time a component 'uses' the x-ray (scatters, detects, ...) within component definitions (see section 6.5). Also, the components to be grouped should be consecutive in the TRACE section of the instrument, and the GROUPed section should not contain components which are not part of the group.

Note that a GROUP construct is *not* applicable to a situation where an x-ray which has interacted (SCATTERed) with one component in the group, may interact with another. In this case a more complex arrangement is needed. See [Wil+11] for a description of how to do this in McStas. This approach is *directly* applicable in McXtrace without modification.

Combining EXTEND, GROUP and WHEN can result in unexpected behaviour. Please read the related warning at the end of section 6.4.5.

6.4.4. Duplication of component instances - COPY

Often, one has a set of similar component instances in an instrument. These could be e.g. a set of identical monochromator blades, or a set of detectors. Together with JUMPs (see below), there is a way to copy a component instance, duplicating a parameter set, as well as any EXTEND, GROUP, JUMP and WHEN keyword. Position (AT) and rotation (ROTATED) specification must be explicitly entered in order to avoid component overlap.

The syntax for instance copy is

```
COMPONENT name = COPY(instance_name)
```

where *instance_name* is the name of a preceeding component instance in the instrument. It may be 'PREVIOUS' as well.

If you would like to change only some of the parameters in the instance copy, you may write, e.g.:

```
COMPONENT name = COPY(instance_name)(par1=0, par2=1)
```

which will override the original instance parameter values. In case EXTEND, GROUP, JUMP and WHEN keywords are defined for the copied instance, these will override the settings from the copied instance.

In the case where there are many duplicated components all originating from the same instance, there is a mechanism for automating copied instance names:

```
COMPONENT COPY(root_name) = COPY(instance_name)
```

will append a unique number to *root_name*, to avoid name conflicts. As a side effect, referring to this component instance (for e.g. further positioning) is not straight forward as the name is determined by McXtrace and does not depend completely on the user's choice, even though the PREVIOUS keyword may still be used. We thus recommend to use this naming mechanism only for components which should not be referred to in the instrument.

This automatic naming may be used anywhere in the TRACE section of the instrument, so that all components which do not need further referral may be labeled as COPY(Origin).

As an example, we show how to have a set of three equivalent pinholes (Slits). Only the first instance of the Slit component is defined explicitly, whereas following instances are copies of that definition. The instance names of Slit components are set automatically.

```
COMPONENT S_in = Arm() AT (...)

COMPONENT S_1 = Slit(radius=0.1)
  AT (0,0,0) RELATIVE PREVIOUS

COMPONENT COPY(S_1) = COPY(S_1)
  AT (0,0,d) RELATIVE PREVIOUS

COMPONENT COPY(S_1) = COPY(S_1)
  AT (0,0,d) RELATIVE PREVIOUS
...
COMPONENT S_Out = Arm() AT (0,0,d) RELATIVE PREVIOUS
```

6.4.5. Conditional components - WHEN

One of the most useful features of the extended McXtrace syntax is the conditional WHEN modifier. This optional keyword comes before the AT-ROTATED positioning. It basically enables the component only when a given condition is true (non null).

```
COMPONENT name = comp( $p_1 = e_1, p_2 = e_2, \dots$ ) WHEN (condition)
```

The condition has the same scope as the EXTEND modifier, i.e. may use component internal variables as well as all the DECLARE instrument variables.

Usage examples could be to have specific monitors only sensitive to selected processes, or to have components which are only present under given circumstances (e.g. removable filter or radial collimator), or to select a sample among a set of choices.

In the following example, an EXTEND block sets a condition when a scattering event is encountered, and the following monitor is then activated.

```
COMPONENT Sample = V_sample(...) AT ...
  EXTEND
  %{
    if (SCATTERED) flag=1; else flag=0;
  %}

COMPONENT MyMon = Monitor(...) WHEN (flag==1)
  AT ...
```

The WHEN keyword only applies to the TRACE section and related EXTEND blocks of instruments/components. Other sections (INITIALIZE, SAVE, MCDISPLAY, FINALLY) are executed independently of the condition. As a side effect, the 3D view of the instrument (`mxdisplay`) will show all components as if all conditions were true.

A usage example of the WHEN keyword can be found in the X-ray site/ESRF/ESRF_ID11 instrument from the `mxgui`, where the source model may be chosen by an external parameter.

The WHEN keyword is compatible with GROUP, and thus may be used to activate/deactivate members in a GROUP just like non-grouped components. Combining WHEN, EXTEND and GROUP can result in unexpected behaviour, please use them with caution! As an example, let a GROUP of components all have the same WHEN condition. If the condition is false, none of the elements SCATTER, meaning that all x-rays will be ABSORBED. As a solution to this problem, we propose to include an EXTENDED Arm component in the GROUP, but with the opposite WHEN condition and a SCATTER keyword in the EXTEND section. This means that when none of the other GROUP elements are present, the Arm will be present and SCATTER.

6.4.6. Component loops and non sequential propagation - JUMP

There are situations in which one would like to repeat a given component many times, or under a given condition. The JUMP modifier is meant for that and should be mentioned after the positioning, GROUP and EXTEND. This breaks the sequential propagation along components in the instrument description. There may be more than one JUMP per component instance.

The jump may depend on a condition:

```
COMPONENT name = comp( $p_1 = e_1, p_2 = e_2, \dots$ ) AT (...) JUMP reference
WHEN condition
```

in which case the instrument TRACE will jump to the *reference* when *condition* is true.

The *reference* may be an instance name, as well as PREVIOUS, PREVIOUS(*n*), MYSELF, NEXT, and NEXT(*n*), where *n* is the index gap to the target either backward (PREVIOUS) or forward (NEXT), so that PREVIOUS(1) is PREVIOUS and NEXT(1) is NEXT. MYSELF means that the component will be iterated as long as the condition is true. This may be a way to handle multiple scattering, if the component has been designed for that.

The jump arrives directly inside the target component, in the local coordinate system (i.e. without applying the AT and ROTATED keywords). In order to better control the target positions, it is *required* that, except for looping MYSELF, the target component type should be an *Arm*. Similarly to the WHEN modifier (see section 6.4.5), JUMP only applies within the TRACE section of the instrument definition. Other sections (INITIALIZE, SAVE, MCDISPLAY, FINALLY) are executed independently of the jump. As a side effect, the 3D view of the instrument `mxdisplay` will show components as if there was no jump. This means that in the following example, the very long mirror 3D view only shows a single mirror element.

It is *not* recommended to use the **JUMP** inside **GROUPs**, as the **JUMP** condition/counter applies to the component instance within its group.

We would like to emphasize the potential errors originating from such jumps. Indeed, imbricating many jumps may lead to situations where it is difficult to understand the flow of the simulation. We thus recommend the usage of **JUMPs** only for experienced and cautious users.

6.4.7. Enhancing statistics reaching components - **SPLIT**

The following method applies when the incoming x-ray event distribution is considered to be representative of the real beam, but x-rays are lost in the course of propagation (with low efficiency processes, absorption, etc). Then, one may think that it's a pity to have so few events reaching the 'interesting' part of the beamline (usually close to the end of the instrument description). If some components make extensive use of random numbers (MC choices), they shuffle this way the distributions, so that identical incoming events will not produce the same outgoing event. In this case, you may want to use a technique known as *stratified sampling* (see chapter 4) which in McXtrace is implemented through the **SPLIT** keyword with the syntax

```
SPLIT r COMPONENT name = comp(...)
```

where the optional number *r* specifies the number of repetitions for each event. Default is *r* = 10. Each x-ray event reaching component *name* will be repeated *r* times with a weight divided by *r*, so that in practice the number of events for the remaining part of the simulation (down to the **END**), will potentially have more statistics. This is only true if following components (and preferably component *name*) use random numbers. You may use this method as many times as you wish in the same instrument, e.g. at the monochromator and sample position. This keyword can also be used within a **GROUP**. The efficiency is roughly *r* raised to the number of occurrences in the instrument, so that enhancing two components with the default *r* = 10 will produce an enhancement effect of 100 wrt. the number of events at the end. The execution time will increase but at a slower rate than the statistical quality, provided that the above criteria are met. If the instrument makes use of global variables - e.g. in conjunction with a **WHEN** or User Variable monitoring (see **Monitor_nD**) - you should take care that these variables are set properly for each **SPLIT** loop, which usually means that they must be reset inside the **SPLITed** section and assigned/used further on.

6.5. Writing component definitions

The purpose of a McXtrace component is to model the interaction of an x-ray with a physical component of a real beamline. Given the state of the incoming x-ray, the component definition calculates the state of the x-ray when it leaves the component. The calculation of the effect of the component on the x-ray is performed by a block of embedded C code. One example of a component definition is given in section 6.5.10. All

other component definitions can be found on the McXtrace web-page [Mcx] and are also described in the McXtrace component manual.

A large number of functions and constants are available in order to write efficient components. See appendix B for

- x-ray propagation functions
- geometric intersection time computations
- mathematical functions
- random number generation
- physical constants
- coordinate retrieval and operations
- file generation routines (for monitors),
- data file reading

6.5.1. The component definition header

```
DEFINE COMPONENT name
```

This marks the beginning of the definition, and defines the name of the component.

```
DEFINITION PARAMETERS ( $d_1, d_2, \dots$ )  
SETTING PARAMETERS ( $s_1, s_2, \dots$ )
```

This declares the definition and setting parameters of the component. These parameters can be accessed from all sections of the component (see below), as well as in **EXTEND** sections of the instrument definition (see section 6.3).

Setting parameters are translated into C variables usually of type **double** in the generated simulation program, so they are usually numbers. Definition parameters are translated into **#define** macro definitions, and so can have any type, including strings, arrays, and function pointers.

However, because of the use of **#define**, definition parameters suffer from the usual problems with C macro definitions. Also, it is not possible to use a general C expression for the value of a definition parameter in the instrument definition, only constants and variable names may be used. For this reason, setting parameters should be used whenever possible.

Outside the **INITIALIZE** section of components, changing setting parameter values only affects the current section.

There are a few cases where the use of definition parameters instead of setting parameters makes sense. If the parameter is not numeric, nor a character string (*i.e.* an array, for example), a setting parameter cannot be used. Also, because of the use of

`#define`, the C compiler can treat definition parameters as constants when the simulation is compiled. For example, if the array sizes of a multidetector are definition parameters, the arrays can be statically allocated in the component `DECLARE` section. If setting parameters were used, it would be necessary to allocate the arrays dynamically using *e.g.* `malloc()`.

Setting parameters may optionally be declared to be of type `int`, `char *` and `string`, just as in the instrument definition (see section 6.3).

`OUTPUT PARAMETERS (s1, s2, ...)`

This declares a list of C identifiers (variables, functions) that are output parameters (*i.e.* global) for the component. Output parameters are used to hold values that are computed by the component itself, rather than being passed as input. This could for example be a count of x-rays in a detector or a constant that is precomputed to speed up computation.

Using `OUTPUT PARAMETERS` is *highly* recommended for `DECLARE` and internal/global component variables and functions in order to prevent that instances of the same component use the same variable names. Moreover (see section 6.5.2 below), these may be accessed from any other instrument part (*e.g.* using the `MC_GETPAR` C macro). On the other hand, the variables from the `SHARE` sections should *not* be defined as `OUTPUT` parameters.

The `OUTPUT PARAMETERS` section is optional.

Optional component parameters

Just as for instrument parameters, the definition and setting parameters of a component may be given a default value. Parameters with default values are called *optional parameters*, and need not be given an explicit value when the component is used in an instrument definition. A parameter is given a default value using the syntax “*param* = *value*”. For example

`SETTING PARAMETERS (radius, height, pack= 1)`

Here `pack` is an optional parameter and if no value is given explicitly, “1” will be used. In contrast, if no value is given for `radius` or `height`, an error message will result.

Optional parameters can greatly increase the convenience for users of components with many parameters that have natural default values which are seldom changed. Optional parameters are also useful to preserve backwards compatibility with old instrument definitions when a component is updated. New parameters can be added with default values that correspond to the old behavior, and existing instrument definitions can be used with the new component without changes.

Optional parameters should not be used in cases where no natural default value exists. For example the size of a slit should not be given a default value. This would prevent the error messages that should be given in the common case of a user forgetting to set an important parameter.

6.5.2. The DECLARE section

```
DECLARE
%{
    ... C code declarations (variables, definitions, functions)...
    ... These are usually OUTPUT parameters to avoid name conflicts
...
%}
```

This gives C declarations of global variables, functions, etc. that are used by the component code. This may for instance be used to declare a x-ray counter for a detector component. This section is optional.

Note that any variables declared in a **DECLARE** section are *global*. Thus a name conflict may occur if two instances of a component are used in the same instrument. To avoid this, variables declared in the **DECLARE** section should be **OUTPUT** parameters of the component because McXtrace will then rename variables to avoid conflicts. For example, a simple detector might be defined as follows:

```
DEFINE COMPONENT Detector
OUTPUT PARAMETERS (counts)
DECLARE
%{
    int counts;
%}
...
```

The idea is that the **counts** variable counts the number of x-rays detected. In the instrument definition, the **counts** parameter may be referenced using the **MC_GETPAR** C macro, as in the following example instrument fragment:

```
COMPONENT d1 = Detector()
...
COMPONENT d2 = Detector()
...
FINALLY
%{
    printf("Detector counts: d1 = %d, d2 = %d\n",
           MC_GETPAR(d1,counts), MC_GETPAR(d2,counts));
%}
```

This way, McXtrace takes care to transparently rename the two 'counts' **OUTPUT** parameters so that they are distinct, and can be accessed from elsewhere in the instrument (**EXTEND**, **FINALLY**, **SAVE**, ...) or from other components. Note that this particular example is obsolete rather artificial since McXtrace monitors will themselves output their contents.

6.5.3. The SHARE section

```
SHARE
%{
    ... C code shared declarations (variables, definitions, functions)...
    ... These should not be OUTPUT parameters ...
%}
```

The **SHARE** section has the same role as **DECLARE** except that when using more than one instance of the component, it is inserted *only once* in the simulation code. No occurrence of the items to be shared should be in the **OUTPUT** parameter list (not to have McXtrace rename the identifiers). This is particularly useful when using many instances of the same component (for instance CRLs) if the declarations were in the **DECLARE** section, McXtrace would duplicate it for each instance (making the simulation code longer). A typical example is to have shared variables, functions, type and structure definitions that may be used from the component **TRACE** section. For an example of **SHARE**, see the samples/Single_crystal component. The `%include "file"` keyword may be used to import a shared library. The **SHARE** section is optional.

6.5.4. The INITIALIZE section

```
INITIALIZE
%{
    ... C code initialization ...
%}
```

This gives C code that will be executed once at the start of the simulation, usually to initialize any variables declared in the **DECLARE** section. This section is optional. Component setting parameters may be modified in this section, affecting the rest of the component.

6.5.5. The TRACE section

```
TRACE
%{
    ... C code to compute x-ray interaction with component ...
%}
```

This performs the actual computation of the interaction between the x-ray and the component. The C code should perform the appropriate calculations and assign the resulting new x-ray state to the state parameters. Most components will require propagation routines to reach the component entrance/area. Special macros `PROP_Z0;` and `PROP_DL();` are provided to automate this process (see section B.1).

The C code may also execute the special macro `ABSORB` to indicate that the x-ray has been absorbed in the component and the simulation of that x-ray will be aborted.

On the other hand, if the x-ray event should be *allowed* be backpropagated, the special macro `ALLOW_BACKPROP`; should precede a call to the `PROP_**` call inside the component.

When the x-ray state is changed or detected, for instance if the component simulates a reflecting mirror, the special macro `SCATTER` should be called. This does not affect the results of the simulation in any way, but it allows the front-end programs to visualize the scattering events properly, and to handle component `GROUPs` in an instrument definition (see section 6.3.5). It basically increments the `SCATTERED` counter. The `SCATTER` macro should be called with the state parameters set to the proper values for the scattering event., so that x-ray events are displayed correctly. For an example of `SCATTER`, see the `optics/Mirror_curved` component. Lately a new keyword `RESTORE` has been added, which generally

6.5.6. The SAVE section

```
SAVE
%{
    ... C code to execute in order to save data ...
%}
```

This gives code that will be executed when the simulation ends, or is requested to save data, for instance when receiving a `USR2` signal (on Unix systems, see section 5.4), or when triggered by the `Progress_bar(flag_save=1)` component. This might be used by monitors and detectors in order to write results. An extension depending on the selected output format (see table ?? and section 5.4) is automatically appended to file names, if these latter do not contain extension.

In order to work properly with the common output file format used in `McXtrace`, all monitor/detector components should use standard macros for writing data in the `SAVE` or `FINALLY` section, as explained below. In the following, we use $N = \sum_i p_i^0$ to denote the count of detected x-ray events, $p = \sum_i p_i$ to denote the sum of the weights of detected x-rays, and $p^2 = \sum_i p_i^2$ to denote the sum of the squares of the weights, as explained in section 4.2.1.

As a default, all monitors using the standard macros will display the integral p of the monitor bins, as well as the 2^{nd} moment σ and the number of statistical events N . This will result in a line such as:

```
Detector: CompName_I=p CompName_ERR= $\sigma$  CompName_N=N "file-
name"
```

For 1D and 2D monitors/detectors, the data histogram store in the files is given *per bin* when the signal is the x-ray intensity (most of the cases). Most monitors define binning for an x_n axis value as the sum of events falling into the $[x_n x_{n+1}]$ range, *i.e* the bins are *not* centered, but left aligned. Using the `Monitor_nD` component, it is possible to monitor other signals using the '`signal=variable_name`' in the 'options' parameter (refer to that component documentation).

Single detectors/monitors The results of a single detector/monitor are written using the following macro:

```
DETECTOR_OUT_OD(t, N, p, p2)
```

Here, *t* is a string giving a short descriptive title for the results, *e.g.* “Single monitor”.

One-dimensional detectors/monitors The results of a one-dimensional detector/monitor are written using the following macro:

```
DETECTOR_OUT_1D(t, xlabel, ylabel, xvar, xmin, xmax, m,  
                EN[0], Ep[0], Ep2[0], filename)
```

Here,

- *t* is a string giving a descriptive title (*e.g.* “Energy monitor”),
- *xlabel* is a string giving a descriptive label for the X axis in a plot (*e.g.* “Energy [meV]”),
- *ylabel* is a string giving a descriptive label for the Y axis of a plot (*e.g.* “Intensity”),
- *xvar* is a string giving the name of the variable on the X axis (*e.g.* “E”),
- *xmin* is the lower limit for the X axis,
- *xmax* is the upper limit for the X axis,
- *m* is the number of elements in the detector arrays,
- *EN*[0] is a pointer to the first element in the array of *N* values for the detector component (or NULL, in which case no error bars will be computed),
- *Ep*[0] is a pointer to the first element in the array of *p* values for the detector component,
- *Ep2*[0] is a pointer to the first element in the array of *p2* values for the detector component (or NULL, in which case no error bars will be computed),
- *filename* is a string giving the name of the file in which to store the data.

Two-dimensional detectors/monitors The results of a two-dimensional detector/monitor are written to a file using the following macro:

```
DETECTOR_OUT_2D(t, xlabel, ylabel, xmin, xmax, ymin, ymax, m, n,  
                EN[0][0], Ep[0][0], Ep2[0][0], filename)
```

Here,

- *t* is a string giving a descriptive title (*e.g.* “PSD monitor”),

- *xlabel* is a string giving a descriptive label for the X axis in a plot (*e.g.* “X position [cm]”),
- *ylabel* is a string giving a descriptive label for the Y axis of a plot (*e.g.* “Y position [cm]”),
- *xmin* is the lower limit for the X axis,
- *xmax* is the upper limit for the X axis,
- *ymin* is the lower limit for the Y axis,
- *ymax* is the upper limit for the Y axis,
- *m* is the number of elements in the detector arrays along the X axis,
- *n* is the number of elements in the detector arrays along the Y axis,
- $\mathcal{E}N[0][0]$ is a pointer to the first element in the array of *N* values for the detector component,
- $\mathcal{E}p[0][0]$ is a pointer to the first element in the array of *p* values for the detector component,
- $\mathcal{E}p2[0][0]$ is a pointer to the first element in the array of *p2* values for the detector component,
- *filename* is a string giving the name of the file in which to store the data.

Note that for a two-dimensional detector array, the first dimension is along the X axis and the second dimension is along the Y axis. This means that element (i_x, i_y) can be obtained as $p[i_x * n + i_y]$ if *p* is a pointer to the first element.

Customizing detectors/monitors Users may want to have additional information than the default one written by the DETECTOR_OUT macros. A mechanism has been implemented for monitor components to output customized meta data. The macro:

DETECTOR_CUSTOM_HEADER(*t*)

defines a string to be written during the next DETECTOR_OUT* call, as a field *custom*. This string should use the symbol %PRE which is replaced by the comment character '#'. The argument *t* to the macro may be a static string, *e.g.* “*My own additional information*”, or the name of a *character array variable* containing the meta data. After the detector/monitor file being written, the custom meta data output is unactivated. This way, each monitor file may have its own meta data definition by repeating the DETECTOR_CUSTOM_HEADER call. You may either do that inside the component SAVE section, or within an instrument description in an EXTEND code preceeding the monitor (*e.g.* following an Arm component).

6.5.7. The FINALLY section

```
FINALLY
%{
    ... C code to execute at end of simulation ...
%}
```

This gives code that will be executed when the simulation has ended. This might be used to free memory and print out final results from components, *e.g.* the simulated intensity in a detector. This section also triggers the SAVE section to be executed.

6.5.8. The MCDISPLAY section

```
MCDISPLAY
%{
    ... C code to draw a sketch of the component ...
%}
```

This gives C code that draws a sketch of the component in the plots produced by the `mxdisplay` front-end (see section 5.5.4). The section can contain arbitrary C code and may refer to the parameters of the component, but usually it will consist of a short sequence of the special commands described below that are available only in the MCDISPLAY section. When drawing components, all distances and positions are in meters and specified in the local coordinate system of the component.

The MCDISPLAY section is optional. If it is omitted, `mxdisplay` will use a default symbol (a small circle) for drawing the component.

The magnify command This command, if present, must be the first in the section. It takes a single argument: a string containing zero or more of the letters “x”, “y” and “z”. It causes the drawing to be enlarged along the specified axis in case `mxdisplay` is called with the `--zoom` option. For example:

```
magnify("xy");
```

The line command The line command takes the following form:

```
line( $x_1$ ,  $y_1$ ,  $z_1$ ,  $x_2$ ,  $y_2$ ,  $z_2$ )
```

It draws a line between the points (x_1, y_1, z_1) and (x_2, y_2, z_2) .

The dashed_line command The dashed_line command takes the following form:

```
dashed_line( $x_1$ ,  $y_1$ ,  $z_1$ ,  $x_2$ ,  $y_2$ ,  $z_2$ ,  $n$ )
```

It draws a dashed line between the points (x_1, y_1, z_1) and (x_2, y_2, z_2) with n equidistant spaces.

The multiline command The `multiline` command takes the following form:

```
multiline(n, x1, y1, z1, ..., xn, yn, zn)
```

It draws a series of lines through the n points $(x_1, y_1, z_1), (x_2, y_2, z_2), \dots, (x_n, y_n, z_n)$. It thus accepts a variable number of arguments depending on the value of n . This exposes one of the nasty quirks of C since *no* type checking is performed by the C compiler. It is thus very important that all arguments to `multiline` (except n) are valid numbers of type `double`. A common mistake is to write

```
multiline(3, x, y, 0, ...)
```

which will silently produce garbage output. This must instead be written as

```
multiline(3, (double)x, (double)y, 0.0, ...)
```

The rectangle command The `rectangle` command takes the following form:

```
rectangle(plane, x, y, z, width, height)
```

Here *plane* should be either "xy", "xz", or "yz". The command draws a rectangle in the specified plane with the center at (x, y, z) and the size $width \times height$. Depending on *plane* the width and height are defined as:

<i>plane</i>	<i>width</i>	<i>height</i>
xy	x	y
xz	x	z
yz	y	z

The box command The `box` command takes the following form:

```
box(x, y, z, xwidth, yheight, zlength)
```

The command draws a box with the center at (x, y, z) and the size $xwidth \times yheight \times zlength$.

The circle command The `circle` command takes the following form:

```
circle(plane, x, y, z, r)
```

Here *plane* should be either "xy", "xz", or "yz". The command draws a circle in the specified plane with the center at (x, y, z) and the radius r .

6.5.9. The end of the component definition

```
END
```

This marks the end of the component definition.

6.5.10. A component example: Semi-transparent mirror

Below is an example of a complete component. A simple example of the component `Semi_mirror` is given.

```

6.6. Extending component definitions

Suppose you are interested in one component in the McXtrace library, but you would like to customize it a little. There are different ways to extend an existing component.

6.6.1. Extending from the instrument definition file

If you only want to *add* something on top of the component existing behaviour, the simplest is to work from the instrument definition `TRACE` section, using the `EXTEND` modifier (see section 6.4.2). You do not need to write a new component definition, but only add a piece of code to execute.

6.6.2. Explicitly modify an existing library component

Copy the interesting component definition from the McXtrace library location (e.g. `/usr/local/mcxtrace/1.2/...` or `c:\mcxtrace\1.2\...`) into your working directory

next to your instrument definition file. This will cause McXtrace to pick this component definition up before the one in the library. Next, modify the local component file until you are satisfied with it. If you feel that the newly modified component may be of use to the McXtrace community, please do not hesitate to contact the development team concerning the options for contributing. Rest assured that copyright remains with you.

6.6.3. Component heritage and duplication

There is a heritage mechanism to create children of existing components. These are exact duplicates of the parent component, but one may override/extend original definitions of any section.

The syntax for a full component child is

```
DEFINE COMPONENT child_name COPY parent_name
```

This single line will copy all parts of the *parent* into the *child*, except for the documentation header.

As for normal component definitions, you may add other parameters, DECLARE, TRACE, ... sections. Each of them will replace or extend (be catenated to, with the COPY/EXTEND keywords, see example below) the corresponding *parent* definition. In practice, you could copy a component and only rewrite some of it, as in the following example:

```
DEFINE COMPONENT child_name COPY parent_name

SETTING PARAMETERS (newpar1, newpar2)
INITIALIZE COPY parent_name EXTEND
%{
    ... C code to be catenated to the parent_name INITIALIZE ...
%}
SAVE
%{
    ... C code to replace the parent_name SAVE ...
%}
```

where two additional parameters have been defined, and should be handled in the extension of the original INITIALIZE section.

On the other hand, if you do not derive a component as a whole from a parent, you may still use specific parts from any component:

```
DEFINE COMPONENT name ...
DECLARE COPY parent1
INITIALIZE COPY parent2 EXTEND
%{
    ... C code to be catenated to the parent2 INITIALIZE ...
%}
TRACE COPY parent3
```

This mechanism may lighten the component code, but a special care should be taken in mixing bits from different sources, specially concerning variables. This may result in difficulties to compile components.

6.7. MxDoc, the McXtrace library documentation tool

McXtrace includes a facility called MxDoc to help maintain documentation of components and instruments. In the source code, comments may be written that follow a particular format understood by MxDoc. The MxDoc facility will read these comments and automatically produce output documentation in various forms. By using the source code itself as the source of documentation, the documentation is much more likely to be a faithful and up-to-date description of how the component/instrument actually works.

Two forms of documentation can be generated. One is the component entry dialog in the `mxgui` front-end, see section 5.5.1. The other is a collection of web pages documenting the components and instruments, handled via the `mxdoc` front-end (see section 5.5.6), and the complete documentation for all available McXtrace components and instruments may be found at the McXtrace webpage [Mcx], as well as in the McXtrace library (see 7.1). All available McXtrace documentation is accessible from the `mxgui` 'Help' menu.

Note that MxDoc-compliant comments in the source code are no substitute for a good reference manual entry. The mathematical equations describing the physics and algorithms of the component should still be written up carefully for inclusion in the component manual. The MxDoc comments are useful for describing the general behaviour of the component, the meaning and units of the input parameters, etc.

The format of the comments in the library source code

The format of the comments understood by MxDoc is mostly straight-forward, and is designed to be easily readable both by humans and by automatic tools. MxDoc has been written to be quite tolerant in terms of how the comments may be formatted and broken across lines. A good way to get a feeling for the format is to study some of the examples in the existing components and instruments. Below, a few notes are listed on the requirements for the comment headers:

The comment syntax uses `%IDENTIFICATION`, `%DESCRIPTION`, `%PARAMETERS`, `%EXAMPLE:`, `%LINKS`, and `%END` keywords to mark different sections of the documentation. Keywords may be abbreviated (except for `%EXAMPLE:`), *e.g.* as `%IDENT` or `%I`.

Additionally, optional keys `%VALIDATION` and `%BUGS` may be found to list validation status and possible bugs in the component.

- In the `%IDENTIFICATION` section, `author:` (or `written by:` for backwards compatibility with old comments) denote author; `date:`, `version:`, and `origin:` are also supported. Any number of `Modified by:` entries may be used to give the revision history. The `author:`, `date:`, etc. entries must all appear on a single line of their own. Everything else in the identification section is part of a "short description" of the component.

- In the %PARAMETERS section, descriptions have the form “*name*: [*unit*] *text*” or “*name*: *text* [*unit*]”. These may span multiple lines, but subsequent lines must be indented by at least four spaces. Note that square brackets [] should be used for units. Normal parentheses are also supported for backwards compatibility, but nested parentheses do not work well.
- The %DESCRIPTION section contains text in free format. The text may contain HTML tags like (to include pictures) and <A>... (for links to other web pages, but see also the %LINK section). In the generated web documentation pages, the text is set in <PRE>...</PRE>, so that the line breaks in the source will be obeyed.
- The %EXAMPLE: lines in instrument headers indicate an example parameter set or command that may be run to test the instrument. A following **Detector:** <name>_I=<value> indicates what value should be obtained for a given monitor. More than one example line may be specified in instruments.
- Any number of %LINK sections may be given; each one contains HTML code that will be put in a list item in the link section of the description web page. This usually consists of an ... pointer to some other source of information.
- Optionally, an %INSTRUMENT_SITE section followed by a single word is used to sort *instruments* by origin/location in the 'X-ray Site' menu in **mxgui**.
- After %END, no more comment text is read by MxDoc.

7. The component library: Abstract

This chapter presents an abstract of the McXtrace component library’s structure and categories. It intentionally does *not* attempt to enumerate every component with its parameter list – the library is large and changes between releases, so any hand-maintained table here would inevitably drift out of date (as earlier editions of this manual did). Instead, each component category chapter that follows (Sources, Optics, Samples, Monitors, ...) documents a curated selection of representative components in depth, with their full, current parameter lists pulled directly from the component source’s McDoc header at build time (see section 6.7 for the McDoc comment format). For the complete, authoritative, always-current list of every component and its parameters, use the `mxdoc` front-end:

```
1 mxdoc
2 mxdoc searchterm
3 mxdoc file .comp
```

The first form generates and opens a browsable *index.html* catalog of the whole library (both the standard installation and any local/custom components); the second searches for and displays documentation for all components matching *searchterm*; the third displays the documentation of one specific component file. See section 5.5.6 in the User Manual for the full `mxdoc` reference.

7.1. Component categories

The library (located under the `mcxtrace-comps` directory of the McXtrace source/installation tree, see section 5.3.2 in the User Manual for how McXtrace locates it) is organised into the following top-level categories:

sources Components that define the initial photon ray state – including point, flat, divergent and full-featured laboratory-source models – see chapter ??.

optics Mirrors, lenses, slits, crystal monochromators, and other beam-manipulating components.

samples Components modelling matter placed in the beam for scattering/absorption studies (SAXS models, powders, single crystals, ...) – see chapter ??.

monitors Components that record/histogram the photon beam without otherwise affecting it.

misc Components that do not fit the other categories, e.g. the `Progress_bar` and beam-statistics utilities.

union The Union framework: a set of process/geometry components that can be freely combined to describe complex, possibly nested and overlapping sample environments with multiple scattering, decoupling the description of *where* matter is from *what* it does to the photon (Compton/Rayleigh scattering, photoelectric absorption, powder diffraction, ...).

sasmodels Small-angle scattering form factors generated from the SasView/sasmodels project, exposed via the `SasView_model` component.

astrox Components specific to the AstroX branch of McXtrace, modelling grazing-incidence X-ray optics for astronomical instrumentation (nested Wolter-type mirror shells, pore and micropore optics).

contrib Components contributed by McXtrace users. The McXtrace core team provides the same technical support as for other categories, but authored and maintained the code less directly; contributed components are generally reliable, but see each component's own validation/bugs notes. Components in **contrib** that mature and gain wide use are periodically promoted into one of the core categories above – always check with `mxdoc` rather than assuming a component's category from an older document.

obsolete Components that were renamed or superseded. They are kept, and continue to work, purely for backwards compatibility with existing instrument files; new instrument development should avoid them (`mxdoc` will point to the current replacement where one exists).

7.2. Data files

Some components require external data files, e.g. atomic form factors, element-specific absorption/refraction data from the NIST database, or multilayer/crystal reflectivity curves. Such files distributed with McXtrace are located in the `data` sub-directory of the library and are accessible to any component using the shared library read routines without needing local copies.

7.3. Component and instrument examples

An overview of the example instrument library, organised by facility and category, is given in the User Manual, chapter ?? . Every `.instr` file there is discoverable via `mxgui`'s **New from Template** menu, or via `mxdoc`.

McXtrace/data	Description
Al.txt, He.txt, etc.	Data files from the NIST database (covering the elements with $Z \in [1..92]$) to be used for absorption and refraction.
FormFactors.txt	Atomic form factors for elements with $Z \in [1..92]$.
Ref_W_B4C.txt	Reflectivity of a W-B4C multilayer.
Ref_W_Si.txt	Reflectivity of a W-Si multilayer.

Table 7.1.: Data files of the McXtrace library.

A. Random numbers in McXtrace

A.1. Transformation of random numbers

In order to perform the Monte Carlo choices, one needs to be able to pick a random number from a given distribution. However, most random number generators only give uniform distributions over a certain interval. We thus need to be able to transform between probability distributions, and we here give a short explanation on how to do this.

Assume that we pick a random number, x , from a distribution $\phi(x)$. We are now interested in the shape of the distribution, $\Psi(y)$, of the transformed $y = f(x)$, assuming $f(x)$ is monotonous. All random numbers lying in the interval $[x; x + dx]$ are transformed to lie within the interval $[y; y + f'(x)dx]$, so the resulting distribution must be $\Psi(y) = \phi(x)/f'(x)$.

If the random number generator selects numbers uniformly in the interval $[0; 1]$, we have $\phi(x) = 1$ (inside the interval; zero outside), and we reach

$$\Psi(y) = \frac{1}{f'(x)} = \frac{d}{dy} f^{-1}(y). \quad (\text{A.1})$$

By indefinite integration we reach

$$\int \Psi(y) dy = f^{-1}(y) = x, \quad (\text{A.2})$$

which is the essential formula for random number transformation, since we in general know $\Psi(y)$ and like to determine the relation $y = f(x)$. Let us illustrate with a few examples of transformations relevant for the McXtrace components.

The circle For finding a random point within the circle of radius R , one would like to choose the polar angle, ϕ , from a uniform distribution in $[0; 2\pi]$, giving $\Psi_\phi = 1/(2\pi)$. and the radius from the (normalised) distribution $\Psi_r = 2r/R^2$.

For the radial part, eq. (A.2) becomes $y/(2\pi) = x$, whence ϕ is found simply by multiplying a random number (x) with 2π .

For the radial part, the left side of eq. (A.2), gives $\int \Psi(r) dr = \int 2r/R^2 dr = r^2/R^2$, which from (A.2) should equal x . Hence we reach the wanted transformation $r = R\sqrt{x}$.

The sphere For finding a random point on the surface of the unit sphere, we need to determine the two angles, (θ, ϕ) .

Ψ_ϕ is chosen from a uniform distribution in $[0; 2\pi]$, giving $\phi = 2\pi x$ as for the circle.

The probability distribution of θ should be $\Psi_\theta = \sin(\theta)$ (for $\theta \in [0; \pi]$), whence by eq. (A.2) $\theta = \cos^{-1}(x)$.

Exponential decay In a simple 2-state model a molecule may be said to relax into its ground state at a time which is exponentially distributed after the initial excitation at $t = 0$. We thus want to pick a relaxation time from the normalised distribution $\Psi(t) = \exp(-t/\tau)/\tau$. Use of Eq. (A.2) gives $x = 1 - \exp(-t/\tau)$. For convenience we now use the random variable $x_1 = 1 - x$ (with the same distributions as x), giving the simple expression $t = -\tau \ln(x_1)$.

Normal distributions The important normal distribution can not be reached as a simple transformation of a uniform distribution. In stead, we rely on a specific algorithm for selecting random numbers with this distribution.

A.2. Random generators

As of McXtrace 3.x, the default random number generator is a 64-bit adaptation of Marsaglia’s *KISS* (“Keep It Simple Stupid”) generator, a composite of a linear congruential generator, a xorshift generator, and a multiply-with-carry generator, combined to give a very long period ($> 2^{127}$) while remaining fast and simple. Crucially, KISS runs identically on both CPU and GPU/OpenACC, which is why it replaced the previously used Mersenne Twister as the default: Mersenne Twister’s large internal state does not parallelize well and is currently not functional for GPU-accelerated simulations.

The classic “Mersenne Twister” generator, by Makoto Matsumoto and Takuji Nishimura[MN98] (see

<http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html> for the original source), remains available as a build-time alternative for CPU-only simulations, selected by compiling the generated instrument with `-DRNG_ALG=1` (e.g. via the `MCXTRACE_CFLAGS` environment variable, or the C-compiler flag options). It has an extremely large period ($2^{19937} - 1$) and negligible cross-correlations up to 623 dimensions, but should not be selected for GPU/OpenACC runs.

B. Libraries and conversion constants

The McXtrace Library contains a number of built-in functions and conversion constants which are useful when constructing components. These are stored in the `share` directory of the `MCXTRACE` library.

Within these functions, the 'Run-time' part is available for all component/instrument descriptions. The other parts are dynamic, that is they are not pre-loaded, but only imported once when a component requests it using the `%include` McXtrace keyword. For instance, within a component C code block, (usually `SHARE` or `DECLARE`):

```
1 %include "read_table-lib"
```

will include the 'read_table-lib.h' file, and the 'read_table-lib.c' (unless the `--no-runtime` option is used with `mcxtrace`). Similarly,

```
1 %include "read_table-lib.h"
```

will *only* include the 'read_table-lib.h'. The library embedding is done only once for all components (like the `SHARE` section). For an example of implementation, see **Res_monitor**.

In this Appendix, we present a short list of both each of the library contents and the run-time features.

B.1. Run-time calls and functions (`mcxtrace-r`)

Here we list a number of preprogrammed macros and functions which may ease the task of writing component and instrument definitions. By convention macros are in upper case whereas functions are in lower case.

B.1.1. Photon propagation

Propagation routines perform all necessary operations to transport x-rays from one point to an other. Except when using the special `ALLOW_BACKPROP`; call prior to executing any `PROP_*` propagation, the x-rays which have negative propagation lengths are removed automatically.

- **ABSORB**. This macro issues an order to the overall McXtrace simulator to interrupt the simulation of the current x-ray history and to start a new one.
- **PROP_Z0**. Propagates the x-ray to the $z = 0$ plane, by adjusting (x, y, z) , ϕ , and t accordingly from knowledge of the x-ray wavevector (kx, ky, kz) . If the propagation length is negative, the x-ray is absorbed, except if a `ALLOW_BACKPROP`; preceeds it.

For components that are centered along the z -axis, use the `_intersect` functions to determine intersection time(s), and then a `PROP_DL` call.

- **PROP_X0, PROP_Y0.** These macros are analogous to `PROP_Z0` except they propagate to the $x = 0$ and $y = 0$ planes respectively.
- **PROP_DL(dl).** Propagates the x-ray by the length dl , adjusting (x, y, z) , ϕ , t accordingly, from knowledge of the x-ray wavevector.
- **ALLOW_BACKPROP.** Indicates that the *next* propagation routine will not remove the x-ray, even if negative propagation lengths are found. Subsequent propagations are not affected.
- **SCATTER.** This macro is used to denote a scattering event inside a component. It should be used to indicate that a component has interacted with the x-ray (e.g. scattered or detected). This does not affect the x-ray state (see, however, **Beam-stop**), and it is mainly used by the `MCDISPLAY` section and the `GROUP` modifier. See also the `SCATTERED` variable (below).

B.1.2. Coordinate and component variable retrieval

- **MC_GETPAR($comp, outpar$).** This may be used in e.g. the `FINALLY` section of an instrument definition to reference the parameters of a component.
- **NAME_CURRENT_COMP** gives the name of the current component as a string.
- **POS_A_CURRENT_COMP** gives the absolute position of the current component. A component of the vector is referred to as `POS_A_CURRENT_COMP. $i$` where i is x , y or z .
- **ROT_A_CURRENT_COMP** and **ROT_R_CURRENT_COMP** give the orientation of the current component as rotation matrices (absolute orientation and the orientation relative to the previous component, respectively). A component of a rotation matrix is referred to as `ROT_A_CURRENT_COMP[ $m$ ][ $n$ ]`, where m and n are 0, 1, or 2 standing for x, y and z coordinates respectively.
- **POS_A_COMP($comp$)** gives the absolute position of the component with the name $comp$. Note that $comp$ is not given as a string. A component of the vector is referred to as `POS_A_COMP( $comp$ ). $i$` where i is x , y or z .
- **ROT_A_COMP($comp$)** and **ROT_R_COMP($comp$)** give the orientation of the component $comp$ as rotation matrices (absolute orientation and the orientation relative to its previous component, respectively). Note that $comp$ is not given as a string. A component of a rotation matrix is referred to as `ROT_A_COMP( $comp$ )[ $m$ ][ $n$ ]`, where m and n are 0, 1, or 2.

- **INDEX_CURRENT_COMP** is the number (index) of the current component (starting from 1).
- **POS_A_COMP_INDEX(*index*)** is the absolute position of component *index*. **POS_A_COMP_INDEX (INDEX_CURRENT_COMP)** is the same as **POS_A_CURRENT_COMP**. You may use **POS_A_COMP_INDEX (INDEX_CURRENT_COMP+1)** to make, for instance, your component access the position of the next component (this is useful for automatic targeting). A component of the vector is referred to as **POS_A_COMP_INDEX(*index*).*i*** where *i* is *x*, *y* or *z*.
- **POS_R_COMP_INDEX** works the same as above, but with relative coordinates.
- **STORE_XRAY(*index*, *x*, *y*, *z*, *kx*, *ky*, *kz*, *phi*, *t*, *Ex*, *Ey*, *Ez*, *p*)** stores the current x-ray state in the trace-history table, in local coordinate system. *index* is usually **INDEX_CURRENT_COMP**. This is automatically done when entering each component of an instrument.
- **RESTORE_XRAY(*index*, *x*, *y*, *z*, *kx*, *ky*, *kz*, *phi*, *t*, *Ex*, *Ey*, *Ez*, *p*)** restores the x-ray state to the one at the input of the component *index*. To ignore a component effect, use **RESTORE_XRAY (INDEX_CURRENT_COMP, *x*, *y*, *z*, *kx*, *ky*, *kz*, *phi*, *Ex*, *Ey*, *Ez*, *p*)** at the end of its **TRACE** section, or in its **EXTEND** section. These x-ray states are in the local component coordinate systems.
- **SCATTERED** is a variable set to 0 when entering a component, which is incremented each time a **SCATTER** event occurs. This may be used in the **EXTEND** sections to determine whether the component interacted with the current x-ray.
- **extend_list(*n*, &*arr*, &*len*, *elemsize*)**. Given an array *arr* with *len* elements each of size *elemsize*, make sure that the array is big enough to hold at least *n* elements, by extending *arr* and *len* if necessary. Typically used when reading a list of numbers from a data file when the length of the file is not known in advance.
- **mcset_ncount(*n*)**. Sets the number of x-ray histories to simulate to *n*.
- **mcget_ncount()**. Returns the number of x-ray histories to simulate (usually set by option **-n**).
- **mcget_run_num()**. Returns the number of x-ray histories that have been simulated until now.

B.1.3. Coordinate transformations

- **coords_set(*x*, *y*, *z*)** returns a **Coord** structure (like **POS_A_CURRENT_COMP**) with *x*, *y* and *z* members.
- **coords_get(*P*, &*x*, &*y*, &*z*)** copies the *x*, *y* and *z* members of the **Coord** structure *P* into *x*, *y*, *z* variables.

- **coords_add**(*a*, *b*), **coords_sub**(*a*, *b*), **coords_neg**(*a*) enable to operate on coordinates, and return the resulting Coord structure.
- **rot_set_rotation**(*Rotation t*, ϕ_x, ϕ_y, ϕ_z) Get transformation matrix for rotation first ϕ_x around x axis, then ϕ_y around y, and last ϕ_z around z. *t* should be a 'Rotation' ([3][3] 'double' matrix).
- **rot_mul**(*Rotation t1*, *Rotation t2*, *Rotation t3*) performs $t3 = t1.t2$.
- **rot_copy**(*Rotation dest*, *Rotation src*) performs $dest = src$ for Rotation arrays.
- **rot_transpose**(*Rotation src*, *Rotation dest*) performs $dest = src^t$.
- **rot_apply**(*Rotation t*, *Coords a*) returns a Coord structure which is $t.a$

B.1.4. Mathematical routines

- **NORM**(*x*, *y*, *z*). Normalizes the vector (*x*, *y*, *z*) to have length 1.
- **scalar_prod**(*a_x*, *a_y*, *a_z*, *b_x*, *b_y*, *b_z*). Returns the scalar product of the two vectors (*a_x*, *a_y*, *a_z*) and (*b_x*, *b_y*, *b_z*).
- **vec_prod**(&*a_x*, &*a_y*, &*a_z*, *b_x*, *b_y*, *b_z*, *c_x*, *c_y*, *c_z*). Sets (*a_x*, *a_y*, *a_z*) equal to the vector product (*b_x*, *b_y*, *b_z*) $\times$ (*c_x*, *c_y*, *c_z*).
- **rotate**(&*x*, &*y*, &*z*, *v_x*, *v_y*, *v_z*, φ , *a_x*, *a_y*, *a_z*). Set (*x*, *y*, *z*) to the result of rotating the vector (*v_x*, *v_y*, *v_z*) the angle φ (in radians) around the vector (*a_x*, *a_y*, *a_z*).
- **normal_vec**(*n_x*, *n_y*, *n_z*, *x*, *y*, *z*). Computes a unit vector (*n_x*, *n_y*, *n_z*) normal to the vector (*x*, *y*, *z*).
- **solve_2nd_order**(**t₀*, **t₁*, *A*, *B*, *C*). Solves the 2nd order equation $At^2+Bt+C=0$ and puts the solutions in **t₀* and **t₁*. The smallest positive solution into pointer **t₀*. If *t₁*=NULL it is ignored and the second solution is discarded.

B.1.5. Output from detectors

Details about using these functions are given in the McXtrace User Manual.

- **DETECTOR_OUT_0D**(...). Used to output the results from a single detector. The name of the detector is output together with the simulated intensity and estimated statistical error. The output is produced in a format that can be read by McXtrace front-end programs.
- **DETECTOR_OUT_1D**(...). Used to output the results from a one-dimensional detector. Integrated intensities error etc. is also reported as for DETECTOR_OUT_0D.
- **DETECTOR_OUT_2D**(...). Used to output the results from a two-dimensional detector. Integrated intensities error etc. is also reported as for DETECTOR_OUT_0D.

- **mcinfo_simulation**(*FILE *f*, *mcformat*, *char *pre*, *char *name*) is used to append the simulation parameters into file *f* (see for instance **Res_monitor**). Internal variable *mcformat* should be used as specified. Please contact the authors for further information.

B.1.6. Ray-geometry intersections

- **inside_rectangle**(*x*, *y*, *xw*, *yh*). Return 1 if $-xw/2 \leq x \leq xw/2$ AND $-yh/2 \leq y \leq yh/2$. Else return 0.
- **box_intersect**(&*l1*, &*l2*, *x*, *y*, *z*, *kx*, *ky*, *kz*, *dx*, *dy*, *dz*). Calculates the (0, 1, or 2) intersections between the x-ray path and a box of dimensions *dx*, *dy*, and *dz*, centered at the origin for a x-ray with the parameters (*x*, *y*, *z*, *kx*, *ky*, *kz*). The intersection lengths are returned in the variables *l1* and *l2*, with $l_1 < l_2$. In the case of less than two intersections, *t1* (and possibly *t2*) are set to zero. The function returns true if the x-ray intersects the box, false otherwise.
- **cylinder_intersect**(&*l1*, &*l2*, *x*, *y*, *z*, *kx*, *ky*, *kz*, *r*, *h*). Similar to **box_intersect**, but using a cylinder of height *h* and radius *r*, centered at the origin.
- **sphere_intersect**(&*l1*, &*l2*, *x*, *y*, *z*, *kx*, *ky*, *kz*, *r*). Similar to **box_intersect**, but using a sphere of radius *r*.
- **ellipsoid_intersect**(&*l1*, &*l2*, *x*, *y*, *z*, *kx*, *ky*, *kz*, *a*, *b*, *c*, *Q*,). Similar to **box_intersect**, but using an ellipsoid with half-axis *a*, *b*, *c* oriented by the rotation matrix *Q*. If $Q = I$, *a* is along the *x*-axis, *b* along *y* and *c* along *z*.

B.1.7. Random numbers

By default McXtrace uses a 64-bit KISS (“Keep It Simple Stupid”) algorithm for generating pseudo random numbers, which runs on both CPU and GPU/OpenACC. The classic Mersenne Twister[MN98] algorithm remains available as a CPU-only, build-time alternative (see chapter A).

- **rand01**(). Returns a random number distributed uniformly between 0 and 1.
- **randnorm**(). Returns a random number from a normal distribution centered around 0 and with $\sigma = 1$. The algorithm used to sample the normal distribution is explained in Ref. [Pre+86, ch.7].
- **randpm1**(). Returns a random number distributed uniformly between -1 and 1.
- **randtriangle**(). Returns a random number from a triangular distribution between -1 and 1.
- **randvec_target_circle**(&*v_x*, &*v_y*, &*v_z*, &*dΩ*, *aim_x*, *aim_y*, *aim_z*, *r_f*). Generates a random vector (*v_x*, *v_y*, *v_z*), of the same length as (*aim_x*, *aim_y*, *aim_z*), which is targeted at a *disk* centered at (*aim_x*, *aim_y*, *aim_z*) with radius *r_f* (in meters),

and perpendicular to the *aim* vector.. All directions that intersect the circle are chosen with equal probability. The solid angle of the circle as seen from the position of the x-ray is returned in $d\Omega$. This routine was previously called **randvec_target_sphere** (which still works).

- **randvec_target_rect_angular**(&*v_x*, &*v_y*, &*v_z*, &*dΩ*, *aim_x*, *aim_y*, *aim_z*, *h*, *w*, *Rot*) does the same as **randvec_target_circle** but targetting at a rectangle with angular dimensions *h* and *w* (in **radians**, not in degrees as other angles). The rotation matrix *Rot* is the coordinate system orientation in the absolute frame, usually ROT_A_CURRENT_COMP.
- **randvec_target_rect**(&*v_x*, &*v_y*, &*v_z*, &*dΩ*, *aim_x*, *aim_y*, *aim_z*, *height*, *width*, *Rot*) is the same as **randvec_target_rect_angular** but *height* and *width* dimensions are given in meters. This function is useful to e.g. target at a guide entry window or analyzer blade.

B.2. Reading a data file into a vector/matrix (Table input, read_table-lib)

The **read_table-lib** library provides functionalities for reading text (and binary) data files. To use this library, add a `%include "read_table-lib"` in your component definition DECLARE or SHARE section. Tables are structures of type **t_Table** (see **read_table-lib.h** file for details):

```

1  /* t_Table structure (most important members) */
2  double *data;      /* Use Table_Index(Table, i j) to extract [i,j]
   element */
3  long    rows;      /* number of rows */
4  long    columns;   /* number of columns */
5  char    *header;   /* the header with comments */
6  char    *filename; /* file name or title */
7  double  min_x;     /* minimum value of 1st column/vector */
8  double  max_x;     /* maximum value of 1st column/vector */

```

Available functions to read *a single* vector/matrix are:

- **Table_Init**(&*Table*, *rows*, *columns*) returns an allocated Table structure. Use *rows* = *columns* = 0 not to allocate memory and return an empty table. Calls to **Table_Init** are *optional*, since initialization is being performed by other functions already.
- **Table_Read**(&*Table*, *filename*, *block*) reads numerical block number *block* (0 to concatenate all) data from *text* file *filename* into *Table*, which is as well initialized in the process. The block number changes when the numerical data changes its size, or a comment is encountered (lines starting by '# ; % /'). If the data could not be read, then *Table.data* is NULL and *Table.rows* = 0. You may then try to read it using **Table_Read_Offset_Binary**. Return value is the number of elements read.

- **Table_Read_Offset**(&Table, filename, block, &offset, n_rows) does the same as Table_Read except that it starts at offset *offset* (0 means beginning of file) and reads *n_rows* lines (0 for all). The *offset* is returned as the final offset reached after reading the *n_rows* lines.
- **Table_Read_Offset_Binary**(&Table, filename, type, block, &offset, n_rows, n_columns) does the same as Table_Read_Offset, but also specifies the *type* of the file (may be "float" or "double"), the number *n_rows* of rows to read, each of them having *n_columns* elements. No text header should be present in the file.
- **Table_Rebin**(&Table) rebins all *Table* rows with increasing, evenly spaced first column (index 0), e.g. before using Table_Value. Linear interpolation is performed for all other columns. The number of bins for the rebinned table is determined from the smallest first column step.
- **Table_Info**(Table) print information about the table *Table*.
- **Table_Index**(Table, m, n) reads the *Table*[m][n] element.
- **Table_Value**(Table, x, n) looks for the closest *x* value in the first column (index 0), and extracts in this row the *n*-th element (starting from 0). The first column is thus the 'x' axis for the data.
- **Table_Free**(&Table) free allocated memory blocks.
- **Table_Value2d**(Table, X, Y) Uses 2D linear interpolation on a Table, from (X,Y) coordinates and returns the corresponding value.

Available functions to read *an array* of vectors/matrices in a *text* file are:

- **Table_Read_Array**(File, &n) read and split *file* into as many blocks as necessary and return a **t_Table** array. Each block contains a single vector/matrix. This only works for text files. The number of blocks is put into *n*.
- **Table_Free_Array**(&Table) free the *Table* array.
- **Table_Info_Array**(&Table) display information about all data blocks.

The format of text files is free. Lines starting by '#' ; '%' '/' characters are considered to be comments, and stored in *Table.header*. Data blocks are vectors and matrices. Block numbers are counted starting from 1, and changing when a comment is found, or the column number changes. For instance, the file 'MCXTRACE/data/Rh.txt' (Material data for Rhodium) looks like:

```

1 #Rh (Z 45)
2 #Atomic weight: A[r] 102.9055
3 #Nominal density: rho 1.2390E+01
4 # sigma[a]( barns/atom) = [mu/rho](cm\^2 g\^-1) . 1.70879E+02
5 # E(eV) [mu/rho](cm\^2 g\^-1) = f[2](e atom\^-1) . 4.08922E+05
6 # 14 edges. Edge energies (keV):

      0.000E+00  7.772E+01
32 1.705382E-02  3.89415E+00  6.8134E+00  1.6337E+05  9.6809E-04  1.6337E+05
      0.000E+00  7.270E+01
33 ...

```

Binary files should be of type "float" (i.e. REAL*32) and "double" (i.e. REAL*64), and should *not* contain text header lines. These files are platform dependent (little or big endian).

The *filename* is first searched into the current directory (and all user additional locations specified using the -I option, see the 'Running McXtrace' chapter in the User Manual), and if not found, in the **data** sub-directory of the **MCXTRACE** library location. This way, you do not need to have local copies of the McXtrace Library Data files (see table 7.1).

A usage example for this library part may be:

```

1  t_Table Table;           // declare a t_Table structure
2  char file []="Rh.txt";  // a file name
3  double x,y;
4
5  Table_Read(&Table, file, 1); // initialize and read the first numerical
   block
6  Table_Info(Table);        // display table informations
7  ...
8  x = Table_Index(Table, 2,5); // read the 3rd row, 6th column element
9                                // of the table. Indexes start at zero in C
10
11 y = Table_Value(Table, 1.45,1); // look for value 1.45 in 1st column (x
   axis)
12
13 Table_Free(&Table);        // and extract 2nd column value of that row
14                             // free allocated memory for table

```

Additionally, if the block number (3rd) argument of **Table_Read** is 0, all blocks will be catenated. The **Table_Value** function assumes that the 'x' axis is the first column (index 0). Other functions are used the same way with a few additional parameters, e.g. specifying an offset for reading files, or reading binary data.

This other example for text files shows how to read many data blocks:

```

1  t_Table *Table;          // declare a t_Table structure array
2  long      n;
3  double y;
4
5  Table = Table_Read_Array("file.dat", &n); // initialize and read the all
   numerical block
6  n = Table_Info_Array(Table); // display informations for all blocks (
   also returns n)
7
8  y = Table_Index(Table[0], 2,5); // read in 1st block the 3rd row, 6th
   column element
9
10 Table_Free_Array(Table); // ONLY use Table[i] with i < n !
11                             // free allocated memory for Table

```

You may look into, for instance, the source files for **Lens_parab** or **Filter** for other implementation examples.

B.3. Constants for unit conversion etc.

The following predefined constants are useful for conversion between units

Name	Value	Conversion from	Conversion to
DEG2RAD	$2\pi/360$	Degrees	Radians
RAD2DEG	$360/(2\pi)$	Radians	Degrees
MIN2RAD	$2\pi/(360 \cdot 60)$	Minutes of arc	Radians
RAD2MIN	$(360 \cdot 60)/(2\pi)$	Radians	Minutes of arc
FWHM2RMS	$1/\sqrt{8 \log(2)}$	Full width half maximum	Root mean square (standard deviation)
RMS2FWHM	$\sqrt{8 \log(2)}$	Root mean square (standard deviation)	Full width half maximum
PI	3.14159265...	π	
CELE	1.602176487e-19	Elementary charge (C)	
M_C	299792458	Speed of light in vacuum (m/s)	
MELECTRON	9.10938291e-31	Electron mass (kg)	
ALPHA	7.2973525698e-3	Fine structure constant, α	
RE	2.8179402894e-5	Thomson scattering length (AA)	
E2K	0.506773091264796	Energy (keV)	Wavenumber (1/AA)
K2E	1.97326972808327	Wavenumber (1/AA)	Energy (keV)

C. The McXtrace terminology

This is a short explanation of phrases and terms which have a specific meaning within McXtrace. We have tried to keep the list as short as possible running the calculated risk that the reader may occasionally miss an explanation. In this case, you are more than welcome to contact the McXtrace core team.

- **Arm** A generic McXtrace component which defines a frame of reference for other components.
- **Component** One unit (*e.g.* optical element) in an x-ray beamline. These are considered as Types of elements to be instantiated in an Instrument description.
- **Component Instance** A named Component (of a given Type) inserted in an Instrument description.
- **Definition parameter** An input parameter for a component. For example the radius of a sample component or the divergence of a collimator. Technically, a definition parameter is translated into a literal constant, which prevents it from being edited at runtime.
- **Input parameter** For a component, either a definition parameter or a setting parameter. These parameters are supplied by the user to define the characteristics of the particular instance of the component definition. For an instrument, a parameter that can be changed at simulation run-time.
- **Instrument** An assembly of McXtrace components defining an x-ray beamline.
- **Kernel** The McXtrace language definition and the associated compiler
- **Output parameter** An output parameter for a component. For example the counts in a monitor. An output parameter may be accessed from the instrument in which the component is used using `MC_GETPAR`.
- **Run-time** C code, contained in the files `mcxtrace-r.c` and `mcxtrace-r.h` included in the McXtrace distribution, that declare functions and variables used by the generated simulations.
- **Setting parameter** Similar to a definition parameter, but with the restriction that the type of the parameter must be declared unless it is a number. In technical terms, a setting parameter is translated into an actual variable (as opposed to a definition parameter) which may be dynamically updated.
